The Indian Ocean is open towards the south, and no considerable island occurs between the meridian of Madagascar and that of the western shores of Australia, as far south as the sea has been navigated (70° S.); on the west is Africa, on the north Arabia, Beloochistan, and Hindustan, and on the east India without the Ganges, the Indian Archipelago, and Australia. The monsoons, however, prevail also in the seas between Australia and China; and these seas are considered as a portion of the Indian Ocean.

The southern part of the Indian Ocean, or that which lies between the western coast of Australia and the island of Madagascar, has the regular south-east trade-wind, which extends southward to between 28° and 30° S. lat., but its northern border varies between 12° and 3° S. lat., approaching nearer to the equator when the sun is in the northern hemisphere. Cook found it, in February, between 10° and 12°; Basil Hall, in June, near 7°; Nicholson, in August, at 3½°; and Carteret, in October, at some distance south of Java.

The monsoons do not begin immediately north of the northern border of the trade-wind, but are separated from it by a region which corresponds with the region of calms in the Atlantic. [CALMS.] Though calms occur in this region of the Indian Ocean also, they are not regular, and are frequently interrupted by winds, which, when the sun is in the northern hemisphere, generally blow between south-west and north-west, and, in the other six months, between south-east and north-east. They are usually called the north-west and north-east monsoons, but not with propriety, as they do not coincide with the proper monsoons in time, nor do they seem to be connected with them in any way.

The region of the proper monsoons lies to the north of this region, and they blow with the greatest force and with most regularity between the eastern coast of Africa and Hindustan. When the sun is in the southern hemisphere a north-east wind, and when it is in the northern hemisphere a south-west wind blows over this sea. When the sun passes the equator the winds are variable, and accompanied with gales, hurricanes, thunder-storms, and calms; but it is observed, that as soon as one of the monsoons ceases, the clouds in the upper regions of the atmosphere take the direction of the opposite monsoon, though it is not till three or four weeks afterwards that this monsoon becomes prevalent on the surface of the sea.

The north-east monsoon blows from November to March. It extends one or two degrees south of the equator. It becomes regular near the coasts of Africa sooner than in the middle of the sea, and near the equator sooner than in the vicinity of the coasts of Arabia. It blows with most regularity and force in the month of January, and especially in the most northern angle of the sea, between the island of Socotra and Bombay. This monsoon is not accompanied with rain on the eastern coast of the sea, but it brings rain to the eastern coast of Africa, where the rainy season falls between the beginning of November and the end of March. It may be laid down as a certain fact that neither of the monsoons brings rain by itself, but only when it reaches a coast after having passed over a wide extent of sea.

The south-west monsoon does not extend south of the equator, but usually begins a short distance north of it. It blows from the latter end of April to the middle of October. Along the coast of Africa, where it rather proceeds from the south, it appears at the end of

March; but along the coast of Malabar, not before the middle of April: it ceases, however, sooner in the former than in the latter region. It is also observed that the south-west monsoon sets in sooner on the coast of Malabar than on that of Canara and Concan. At Anjengo (in 8° 30' N. lat.) it makes its appearance on the 12th of April, and at Bombay on the 15th of April, so that it proceeds a degree farther northward in the course of three days. It reaches the coast of Arabia still later. On the sea it is a serene wind of moderate force; but when it approaches the coast of Hindustan, the atmosphere becomes overcharged with moisture, and the rain descends in torrents, but more abundantly on the southern than on the northern coast. Near Tellicherry, the annual quantity of rain amounts to 116 inches, but at Bombay it does not exceed 63 inches. It was formerly supposed that the south-west monsoon was arrested by the Western Ghats, but a better acquaintance with the table-land of Deccan has shown that the greatest quantity of rain descends on it during the south-west monsoon, and with a wind blowing from south-west. It has latterly been observed that its effects extend to the coast of Coromandel, where, during its prevalence, a few showers fall. But the farther this monsoon advances into the continent, the smaller is the quantity of rain which it causes. Northward its effects extend over the table-land of Malwa, the low country along the course of the Indus, and even to the coast of Beloochistan, as far as the Straits of Ormuz.

Both monsoons occur in the Bay of Bengal, but there they are somewhat modified and less regular. The north-east monsoon does not set in regularly before the beginning of December, when it blows from north-north-east and east-north-east. In January and February it is irregular, and frequently turns to the south-east; and in March it ceases entirely in the centre of the sea, and blows faintly in the north-eastern parts, with long intervals of calms. Though the north-east monsoon only becomes regular in December, it is preceded by heavy squalls and winds in the southern parts, especially along the coast of Coromandel; and it is during these squalls that this part of Hindustan is fertilised by abundant rains, which however are less plentiful than those brought to the coast of Malabar by the south-west monsoon. The mean annual quantity of rain at Madras does not exceed 46 inches. The south-west monsoon is more regular in its strength, but not in its direction, as it blows frequently from the south, and even from south-east, especially near the mouth of the Ganges. Little rain falls during this wind on the west coast of the Gulf of Bengal; but rain is abundant in the countries which enclose it on the north, in which direction it extends to the foot and declivities of the Himalaya mountains, and as far as the place where the Ganges issues from the range; but here too the quantity decreases as it advances inland. The mean annual quantity of rain at Calcutta is nearly 72 inches, and at Benares 46½ inches. The quantity of rain which, during this monsoon, descends on the eastern coast of the bay, is still larger, especially towards its northern recess, in Chittagong and Aracan, where, according to a rough estimate, founded on partial observations, it amounts annually to 200 inches.

The monsoons are subject to much greater variation to the east of the Bay of Bengal. In the Chinese Sea and the Sooloo Sea the wind is south-south-east when the sun is in the northern hemisphere, but it does not blow with regular force, being sometimes interrupted by high winds. It brings rain to all the countries which surround the sea on the north and east. In the southern provinces of China, in the Philippine Islands, and in the Sooloo Islands, the rainy season commences in the beginning of May, and terminates in September and October. The rains, though rather abundant, when compared with those which fall in the countries without the tropics, are much inferior in quantity to the rains in Bengal and Chittagong. It is remarkable that these rains extend to the countries surrounding the Gulf of Tonkin. The monsoon blows in these seas from north-north-west when the sun is in the southern hemisphere; but it is still less regular in its force, though more so than in the Bay of Bengal. It brings rain to the countries on the west and south of the sea, and especially to the coast of Cochin China Proper and the northern shores of Borneo, where the rains commence at the end of October and continue until March. They are more abundant than those which fall during the opposite monsoon on the northern and eastern shores of the Chinese Sea.

Along the equator, and about one or two degrees from it, it appears that the winds are subject to frequent changes; and it is also observed that the islands situated within these limits have frequent showers nearly every day in the year.

In the Java Sea and the southern parts of the straits which lead from that sea to the Chinese Sea, the wind generally blows from the west when the sun is in the southern hemisphere, and from the east when it is in the northern hemisphere; but it turns frequently to the north-west and south-east, which is also the case with the winds in the sea south of Java, and between the Lesser Sunda Islands and Australia. The westerly winds bring rain to these islands, but not in such abundance, as the south-west monsoon carries them to Malabar. During the easterly winds the air is generally dry, but sometimes there are heavy-showers. In these islands neither season has that decided permanent character which distinguishes it on the continent of India, and the rains are far from being so violent. But the northern coast of Australia partakes more of the character of the season of the continent of India. The rains indeed do not seem to come down with such violence; not a drop falls during June, July, August, and September

* At Athens there was a law which limited the amount of corn that a man could buy. (Lysias, *κατὰ τῶν σιτοπωλῶν*.)

which is also sometimes the case in Java and the Lesser Sunda Islands.

The direction of the monsoons in the vicinity of the land is frequently changed by the direction of the coast, especially when a mountain range extends along the shores. The most remarkable instance of this phenomenon is observed on the south-western coast of the island of Sumatra. The south-west monsoon is felt at Acheen Head, its most northern point; but, being opposed by the range of high mountains running along the south-western coast, it is changed into a north-west wind, which blows as far south as 1° N. lat. South of the equator the wind is not south-west, but south-east, and may be considered as the trade-wind, which, as already observed, extends as far north as 3° S. lat. when the sun is in the northern hemisphere. During this period that part of the island which lies north of the equator has its rainy season, whilst the southern districts have dry weather. When the sun is in the northern hemisphere the southern portion has abundant rains, with frequent thunder-storms; and the northern enjoys a serene sky. In that season of the year the wind blows in the southern part from north west, and is that wind which is generally called the north-west monsoon; but the northern districts are under the influence of the north-east monsoon.

It is not easy to explain the origin of these periodical winds. It is admitted on all hands that they are only a modification of the trade-winds, produced by the peculiar form of the countries lying within and around the Indian Ocean. This modification, it is said, is produced by the difference of temperature to which the high table-lands of Asia and Africa are subject during the two great divisions of the year. When the sun is in the northern hemisphere the heat causes such a rarefaction of the atmosphere on the table-land of Asia as to make the air flow rapidly from the colder region near the equator to that quarter; and this is the south-west monsoon. When, on the contrary, the sun, during its stay in the southern hemisphere, heats the air on the table-land of southern Africa, the contrary effect takes place, and that is the north-east monsoon. This explanation however is hardly satisfactory. It is a fact that on the high table-lands the air is always in a state of rarefaction, compared with that of low countries, and that the summer-heat is never such as to cause a degree of rarefaction sufficient to produce a motion in the air from the lower countries towards the table-lands. Besides this, the Himalaya mountains, with their immensely high masses, lie in the line in which the south-west monsoon blows, and its effects are not observed to be sensible in the higher part of that range. The table-lands of Beloochistan and Arabia cannot be considered as affecting the direction of the wind, for in that case the wind would rather blow from the south-east than from the south-west. We think therefore that the cause of this modification of the trade-wind must be sought for in less remote localities. As for the north-east monsoon, we are inclined to consider it entirely as a continuation of the north-east trade-wind, which is only interrupted by the two peninsulas stretching southward into the Indian Ocean; and this interruption is the cause why it is commonly less constant and regular than the trade-wind itself. The question therefore is only why this trade-wind is interrupted by a wind blowing in an opposite direction when the sun is in the northern hemisphere. In this part of the year the trade-wind in the northern hemisphere retires thirteen degrees from the equator. If this fact is applied to the Indian Ocean, only the most northern recesses of the three gulfs, the Arabian Sea, the Bay of Bengal, and the Chinese Sea, would fall within its limits, and the remainder would be within the region of calms. In such a state of indifference a less powerful agency may produce a great effect. The south-east trade-wind, which, when the sun is on the north of the equator, extends to the vicinity of the equator, is prevented by the elevated table-land of Africa from proceeding in its direction, and is therefore diverted from its course. It follows the winding of the coast to the north-east; but as the coast of Africa, as well as that of Arabia, is skirted by very high mountains, it finds no way to escape in a western direction. It would however probably not acquire that degree of constancy and force by which it is characterised, if it did not blow towards a country in which a considerable rarefaction of the air is produced by the sun's approaching to the northern tropic. This is the Indian Desert, called Thurr, in which the heat in summer rises to an excessive degree, on account of its small elevation above the sea, its sandy soil, and the almost complete want of vegetation. The rarefaction produced by this heat gives strength and constancy to the south-west monsoon, and carries it to the very base of the Himalaya mountains, though the desert itself does not partake of the fertilising rains which this monsoon brings to all the coast whose mountains oppose its progress. This, we think, is sufficient to explain the south-west monsoon in the Arabian Sea, where it is most constant and regular.

The south-east trade-wind, not extending to the north of the equator, cannot be considered as contributing to produce the south-west monsoon in the Bay of Bengal; and this wind therefore seems to owe its existence merely to the rarefaction of the air produced by the summer-heat in the wide plain of the Ganges; but as this plain is partly covered with trees (Sunderbund and Terai) and nearly everywhere with vegetation, the effect of the heat on the temperature of the air is less regular; and thus it may be explained that the south-west monsoon in this sea is less regular and constant. The vegetation

which covers the Gangetic Plain is probably also the reason why the rains brought by the monsoon are distributed over its whole extent, whilst it passes over the dry sands of the Thurr almost without letting a single shower fall.

The origin of the south monsoon in the Chinese Sea is more difficult to explain. The great plain of Siam and Camboja, the mountain-range of Cochin China, which extends along the shores of the sea from south to north, and the plains of Tonquin, probably contribute largely to it; but we are too imperfectly acquainted with the extent and nature of these plains to be able to form a correct opinion on this point. That this south monsoon extends to the island of Formosa can hardly be adduced as an objection to this explanation, when it is considered that the north-east trade-wind retires to the most northern corner of the Chinese Sea, and is there very feeble and irregular.

As for the monsoons of the Java Sea and of the seas between the Lesser Sunda Islands and Australia, they seem to owe their origin principally to the changes of temperature which occur in the countries lying along the northern coast of Australia. [WIND.]

MONSTRANS DE DROIT. [PETITION OF RIGHT.]

MONT DE PIETÉ' (MONTE DI PIETÀ, in Italian), is the title of certain pawnbroking establishments which originated in Italy in the 15th century, the object of which was to lend money to necessitous people at a moderate interest. The Jews, who were the great money-lenders in that age, exacted an enormous interest, as much as 20 to 25 per cent. The Papal government and other Italian governments established a kind of bank, which lent money upon pledges, for a fixed term, at a low rate of interest, intended chiefly to defray the unavoidable expenses of the establishment; at the expiration of which term, if the capital lent and interest were not repaid, the pledges were sold, and the surplus money, after paying the debt incurred, was restored to the owners. In most instances however the term might be renewed by merely paying the interest. The administration of the Monte di Pietà was to be conducted upon economical and strictly equitable principles, and it was under the inspection of the government as a public benevolent institution. This at least was the original principle, although occasionally deviated from in consequence of the cupidity or necessities of the governments themselves.

This institution was introduced into other countries, especially into Flanders. In Spain there were also similar establishments at Madrid and some other large towns, but in no country were they so generally spread as in Italy.

When the French under Bonaparte invaded Italy in 1796-7, they plundered the Monti di Pietà of Milan, Modena, Parma, and most other towns. At Rome, Pope Pius VI., being pressed by the French to pay an enormous sum for war contributions, was obliged to seize upon the richer pledges in the Monte di Pietà, for the repayment of which he gave bonds; but these bonds lost all value in the subsequent invasion of Rome by the French in 1798. The Monti di Pietà have been re-established in some of the Italian cities, and there is an institution of a similar character in Paris.

MONTANISTS. [MONTANUS, in BIOG. DIV.]

MONTEM CUSTOM, the ancient custom of a procession of the scholars of Eton School in Buckinghamshire *ad montem*, which has been discontinued since 1844. It used to be made every third year, on Whit-Tuesday, to a tumulus near the Bath Road, which has acquired the name of Salt Hill, by which also the neighbouring inns have been long known. The chief object of the celebration was to collect money for salt, as the phrase is, from all persons present, and it was exacted even from passengers travelling the road. The scholars who collected the money were called salt-bearers, and they, as well as others of the scholars, especially the captain, who was the senior scholar, the ensign, whose duty it was to flourish a flag on the mount, and the scouts, who collected the salt, were dressed in fanciful rich habits, generally military. Tickets inscribed with some motto, such as *Ad Montem, Mos pro Lege*, or *Pro More et Monte*, by way of pass-word, were given to such persons as had already paid for salt, as a security from any further demands.

This ceremony has been frequently honoured with the presence of the sovereign and the royal family, whose liberal contributions added to those of many of the nobility and others who had been educated at Eton, so far augmented the general collection that it has been known to amount to near 1000*l*. The sum so collected was given to the captain of the school, or senior scholar, who was going off to Cambridge, for his support at the university. It would be in vain, perhaps, to trace the origin of all the circumstances of this singular custom, particularly that of collecting money for salt, which had been in use from time immemorial. The procession itself seems to have been coeval with the foundation of the college, and it has been conjectured, with much probability, that it was that of the *Bairn*, or *Boy-bishop*. It originally took place on the 6th of December, the festival of St. Nicholas, the patron of children, being the day on which it was customary at Salisbury, and in other places where the ceremony was observed, to elect the Boy-bishop from among the children belonging to the cathedral. It is only since 1759 that the time of the celebration of the Eton Montem was changed, and in 1778 it appears to have been held biennially. It was formerly a part of the ceremony that a boy dressed in a clerical habit, with a wig, should read prayers.

MONTH. [MOON; YEAR.]

MOOD, or MODE. [VERB.]

MOON (Latin *Luna*, Greek *σελήνη*, *sēlēnē*), the satellite of the earth, a heavenly body which moves round the earth, sharing the motion of the earth round the sun.

In a day or two (depending on the state of the weather) from the time called in the almanacs "the new moon," a thin silver crescent is seen with its horns turned from the sun and placed to the eastward of the sun, after which it soon sets. Its distance from the sun increases, the horns at the same time growing fuller, until, in $7\frac{1}{4}$ days, it is at ninety degrees (or as far as from the horizon to the zenith) distant from the sun, and the crescent has become a semicircle of white light. The distance still increases, until the moon is 180° distant from the sun, or in the opposite part of the heavens, by which time the light part has become a full circle: this happens in somewhat more than $14\frac{1}{2}$ days from the new moon. The satellite still continues its revolution among the stars, becoming westward of the sun after the full moon, and, decreasing by the same steps as it increased, is lost a day or two before the time which the almanacs point out as the next new moon. The whole of this process takes up what is called a *lunation*, or a *lunar month*: the lunar months are slightly unequal, but their average period is 29 days, 12 hours, 44 minutes, $2\frac{9}{10}$ seconds, or 29.5305887215 mean solar days. To show the irregularity of the lunations, we give the times of all the new moons which take place in the years 1860 and 1861, with the intervals.

NEW MOONS. 1860, 1861.

It appears then not only that the lunar month varies, but that there is no yearly cycle of variation. Before however we make any remark on the preceding, we shall place by its side materials for confidence in the almanac from whence the preceding times were quoted. Taking at hazard a volume of astronomical observations, and opening the part where the results of the lunar observations are found, we took the first right ascensions [ASCENSIONS] of the moon which we came to, opposite to which, for comparison, were written the predicted right ascensions of the moon for the same times. The dates matter nothing, since it is only the accordance of prediction with observation which is to be noticed. ('Camb. Obs.,' 1835.)

Predicted R.A.	Observed R.A.	Difference.
h m s	h m s	
14 23 57.87	14 23 57.61	26-100ths of a second.
23 1 59.84	23 1 58.55	1 st and 29-100ths.
4 56 13.31	4 56 14.01	7-10ths of a second.
18 7 40.74	18 7 40.50	24-100ths of a second.

The lunar theory then, resting upon the Newtonian doctrine, enables astronomers to find the position of the moon within a part of the heavens answering to a second of diurnal revolution, while the rough observations with which astronomy must always commence would not give the length of a lunation within an hour. It is also confidently expected that the lunar tables recently computed by Professor Hansen of Gotha, in accordance with his lunar theory, and printed at the expense of the British government, will, from their superiority, ensure a degree of accuracy of prediction hitherto unprecedented.

Taking the lunar phenomena in the order of discovery, we next notice that this planet writes its mark on the earth in terms which have been understood from the earliest ages of astronomical inquiry. The alternate rise and fall of the waters, called the *tides*, is found to follow its motions, so that high water is always found to succeed the time when the moon comes on the meridian, whether on the visible or invisible side of it. At first sight it would appear that there is high water twice a-day (that is, in the common solar day), but it is found on further examination that the interval between high water and high water is a little more than twelve hours; so that in the year 1858 that

phenomenon occurred only 705 instead of 730 (twice 365) times. Now the motion of the moon round the heavens is found to take place (one time with another) in 27.32166142 solar days (we shall presently see why this is not a lunation), which gives $13^\circ 10' 35''$ increase of right ascension in each solar day, or $13^\circ 8' 23''$ in a sidereal day, or actual revolution of the earth. Hence the meridian of the spectator, between two times at which the moon is on the visible side of that meridian, must make so much more revolution as is necessary to overtake a body which revolves through $13^\circ 8' 23''$ while it revolves through 360° ; which gives $24^h 55^m$ of a revolution of the earth for each lunar day, or $12^h 27\frac{1}{2}^m$ for its half. Now the year contains $366\frac{1}{4}$ sidereal days, or simple revolutions of the earth; and it will be found that $12^h 27\frac{1}{2}^m$ is contained 705 times and a fraction in $366\frac{1}{4}^d$. As every reader may not be acquainted with the distinction of sidereal and solar time, we may here simply state (referring to SUN and TIME for detail) that the common day is not the simple revolution of the earth, but includes the additional time in which the meridian overtakes the sun, which has moved forward about a degree. Thus it appears, that even on a single year the coincidence of half a lunar day and the interval between two times of high water is sufficiently apparent. It may be said that we have assumed the question by counting the times of high water from an almanac constructed on the supposition which we wished to establish. This would be true if we had talked of the year 1860; but we may consider an almanac for 1858 as now a verified prediction: it would have made no small noise in the public papers if there had been a tide more or less in the Thames than was predicted in the almanacs. The theory of the tides is the most difficult in astronomy, owing to the disturbing action of winds, channels, &c., as well as its intrinsic mathematical difficulties; but this one phenomenon has never had its exception in open sea—that every transit of the moon over (either side of) the meridian is followed by the rise of the water, though so high a wind has been known as to prevent the tide coming up a river.

We return to the phenomena of the *phases* (Greek for appearances), as they are called, of the moon, namely, the changes in the quantity of its illuminated part. These may be immediately explained on the supposition that the moon is not luminous itself, but receives its light from the sun.

To show how this may be, suppose a ball, illuminated by another ball at a great distance in the direction ES, to be carried round the spectator at E. This ball may be always subdivided into a visible and in-

visible half, since one-half must hide the other in all positions. But it may also be divided into an illuminated and unilluminated half. At A the visible half is all unilluminated, and though we have called it the visible half (meaning in a position to be seen, if there were light), it will not be seen. But when the ball arrives at B, a small portion of the illuminated half is in the visible half, as much as is intercepted between the arrows. At D a larger portion of the illuminated part is visible, and at F a full half of the visible surface is illuminated. A little consideration of this scheme (which is moreover explained in all popular works) will show not only the occurrence of phases precisely similar to those of the moon, but also that the circular boundary of the enlightened part is towards the illuminating body. We copy from Riccioli his collection of the Latin and Greek terms used with respect to the different phases:—

A Novilunium, luna silens, Conjunctio, Congressus cum sole, Neomenia, Synodus, Lunæ accensio.	{ νεομηνία νομηνία σύνοδος
B Prima phasis, Nova luna.	{ πρώτη φάσις νέα σελήνη
C Ultima phasis.	{ ἐσχάτη φάσις ἐξη σελήνη
Luna novissima, Interlunium, seu intermenstruum, est tempus inter ultimam et primam phasim, à C ad B.	{ ἀφανισμὸς

with the sun. 3. The average *anomalistic* month, or revolution from perigee to perigee. 4. The average *tropical* month, or from the vernal equinox to the vernal equinox again (the equinox being in retrograde motion [PRECESSION]). 5. The average *nodical* month, or from a node to a node of the same kind. The quantities of these months are as follows (Baily, 'Astron. Tables and Formulæ') in mean solar days:—

	d	h	m	s	d
Sidereal month	27	7	43	11.5	or 27.32166142
Lunation	29	12	44	2.9	„ 29.53058872
Anomalistic month	27	13	18	37.4	„ 27.55459950
Tropical month	27	7	43	4.7	„ 27.32158242
Nodical month	27	5	5	36.0	„ 27.21222222

If we compare the lunation with the common year, we shall find that 235 lunations make 6939.69 days, while 19 years make 6939 or 6940 days, according as there are four or five leap-years in the number. Neither is wrong by a day; consequently in 19 years the new and full moons are restored to the same days of the year. This does not absolutely follow, either from the preceding or from the method which gave it, since neither is the coincidence exact, nor are the months exactly equal. But it will generally so happen; and this is the foundation of the *Metonic Cycle*. [CALIPPUS and METON, in BIOG. DIV.] Again, 223 lunations make 6585.322 days, and 242 nodical revolutions make 6585.357 days, so that there is only .035 of a day, or 50 minutes, difference between the two. This period of 223 lunations is the *SAROS*, a celebrated Chaldean period, and contains in round numbers of days 18 years and 10 days, or 18 years and 11 days, according as there are five or four leap-years. It may be worth while to express these numbers of lunations in terms of the other months.

Metonic Cycle.—235 lunations make 253.999 sidereal months, 251.852 anomalistic months, and 255.021 nodical months.

Saros.—223 lunations make 241.029 sidereal months, 238.992 anomalistic months, and 241.999 nodical months.

The rate at which the moon moves is different in different parts of the orbit. We may speak either of the rate at which she changes longitude, latitude, or distance from the earth; and owing to the smallness of the inclination of her path to the ecliptic, her motion in longitude is nearly the same thing as her motion in her own orbit. The quickest motion is at or near the perigee, and the slowest at or near the apogee. The moon's rate of motion follows no easily obtainable law in its changes, which are different in different months. The rate of change of latitude is greatest near the nodes, and the rate of change of distance from the earth is least at the apogee and perigee, and greatest at and about the intermediate points. We have hitherto considered the apparent path of the moon among the stars: we now pass to the real orbit in space. Her average distance from the earth is 29.982175 times the equatorial diameter of the earth, which makes about 60 radii of the earth, or 237,000 miles. But the radius of the sun's body is 111½ times the radius of the earth: so that a large sphere, which, having its centre in the earth, should contain every part of the moon's orbit, would not be a quarter of the size of the sun.

Again, the sun's distance is 23,984 radii of the earth, or nearly 400 times the moon's average distance. A good idea of the relative magnitudes of the distances may be obtained as follows:—Take a ball one inch in diameter to be the sun, and another of half an inch in diameter to be the sphere which envelopes the moon's real orbit; place these nine feet apart, and a proper idea of the distance of the sun, compared with its size and that of the moon's orbit, will be obtained.

To form a sufficient notion of the real orbit, imagine another body, directly under the moon on the plane of the ecliptic, to accompany her in her motion. Let *SSSS* represent the plane of the ecliptic, in which the sun must be, and *ALB* a part of the real orbit, from an ascending to a descending node; *L* being a position of the moon, *P* is

the projected body on the plane of the ecliptic; and the motion of *P* will be very nearly that of *L*, owing to the smallness of the rise of *ALB* above the plane of the ecliptic. The motion of the projected body will then be of the kind of which the following diagram is an exaggeration.

Suppose the moon to set out from 1 on the left, being then in apogee, and also at a node: the projected body will then describe 1 1 1, &c., until it comes to its perigee at the first 2, which is in advance of the point opposite to the apogee. But the real moon will have come to the plane of the ecliptic before it is opposite to the first 1, so that at the first 2 the moon will be below the projected orbit. The projected body then describes 2 2 2... up to the next apogee 3, and so on; the

real moon having come above the ecliptic before the last 2 but one. In the present figure the number of folds is limited, and the last joins

the first; in the moon's orbit the number of folds is unlimited. The real relation between the greatest and least distances is slightly variable in the different folds; one with another it may be thus stated: 5½ per cent. being added to the mean distance will give the greatest or apogean distance, and subtracted, the least or perigean distance. Taking the fiction of the moving ellipse for the moon's orbit, its eccentricity is .0548442.

In the article GRAVITATION will be found a sketch of the producing causes of the inequality of the lunar motions, showing that they arise from the effect of the sun's unequal attraction of the earth and moon; were it not for which, the latter would describe an ellipse round the former. In the present article we intend only to describe the motions themselves. We have pointed out both the apparent orbit in the heavens, and the real orbit: It remains to ask, In which manner is the real orbit described? At a given time, how is the moon's place in the heavens to be ascertained?

Returning again to the apparent orbit, we first consider motion in longitude only; that is we ask how to find the moon's longitude at the end of a given time. Let us suppose then that, *Q* being the apparent place of the moon in the heavens, we draw *QM* on the sphere perpendicular to the ecliptic, so that *M* has the same longitude as *Q*. To connect this figure with the last, suppose that the moon was at *L* when it was projected in the heavens to *Q*, and let *P* be the projection of *L* on the ecliptic: then *P* will be thrown upon *M* in the heavens. The average motion of *M* will be that of the moon, or a circuit in 27.32166 days. If then we were to suppose a fictitious moon setting out from *M*, and moving with this average motion, it would never be far from the point *M*; which last, from the irregularity of the real moon's motion, would be sometimes before and sometimes behind the fictitious moon.

If we could observe the fictitious moon, thus regularly moving in the ecliptic (say every day at midnight), and also the real moon, we might take a long series of years' observations, and sum all the excesses of *M*'s longitude over that of the fictitious body, when there are excesses, and all the defects when there are defects. We might expect to find the one sum equal to the other; but we are taught by the theory (which, as before seen, is exact enough to find the moon's place within a second) that the equality of these sums will not be absolutely attained in any series of years, however great, if we take the commencing point, at which *M* is to coincide with the fictitious body, at our own caprice. Wherever *Q* may be, there is a proper place for this fictitious moon, before or behind *M*, from which if we allow the former to start, the longer we go on with the series of supposed observations, the more nearly will the excesses balance the defects; supposing always that our series of observations stops at the end of a complete number of circuits, and not in the middle of one. This position is called the *mean place* of the moon, as distinguished from *Q*, its *real place*. Let us suppose it to be at *v*; then if the average moon start from *v*, with the moon's average motion, it will at every instant of time point out what is called the mean place of the moon corresponding to the then real place. At the commencement of the present century, that is, when it was 12 o'clock at Greenwich on the night of December 31, 1800, the longitude of the average moon, or the moon's mean longitude, was (according to Burckhardt) 118° 17' 3";

and the mean longitude at any other time is found by adding in the proportion of 4809°38'468 for every 365 days, and making the necessary additive allowance for the precession of the equinoxes. [PRECESSION]

In the same way the node and perigee of the moon have their mean places, and, as we have seen, their mean motions. The mean longitude of the perigee, at the commencement of the century, was 266°10'7"5; that of the ascending node 13°53'22"2.

To the above must be added that these average motions, as they are called, are subject to a slight acceleration, which hardly shows itself in a century; that of the longitude was detected by Halley from the comparison of some Chaldean eclipses with those of modern times. This acceleration would, in a century, increase the mean longitude of the moon by 11", that of the perigee by 50", and that of the ascending node by 7".

The mean longitude being ascertained for the given time, the true longitude is found by applying a large number of corrections, as they are called, some determined from the theory of gravitation, but the larger ones, as might be supposed, detected by observation before that theory was discovered, and since confirmed by it. Into this subject it will be impossible to enter at length; we shall therefore merely instance a few of the principal corrections for the longitude, observing that the latitude, the distance, &c., are all determined by adding or subtracting a number of corrections from the results of the supposition that the moon moves uniformly in the ecliptic at her average distance from the earth.

The first correction is one which brings the motion nearer to an elliptical one, and is called the *equation of the centre*. It depends upon the moon's distance from her perigee, called the anomaly. The *mean anomaly* is the distance of the moon's mean place from that of the perigee. The mathematical expression is (we give only rough constants)—

$$6^{\circ} 17' \times \sin (\text{mean anomaly}).$$

The second correction, known as the *evection*, and discovered by Ptolemy, is—

$$1^{\circ} 16' \times \sin \{ 2 (\odot - \ominus) - \text{mean anomaly} \}$$

where $\odot$ and $\ominus$ stand for the mean longitudes of the moon and sun.

The *variation* and the *annual equation* (discovered by Tycho Brahé) are represented by

$$39' \times \sin 2 (\odot - \ominus)$$

and

$$11' \times \sin (\odot \text{'s mean anomaly}).$$

Many such corrections (but those which remain, of less amount) must be added to or subtracted from the mean longitude before the true longitude can be determined.

Having thus noticed the actual motions of the moon, we proceed to the phenomena of eclipses, and of the harvest-moon, as it is called. An eclipse of the moon has now lost most of its astronomical importance, and can only be useful as an occasional method of finding longitude, when no better is at hand. Eclipses of the sun, observed in a particular way, may be made useful in the correction of the theory both of the sun and moon; in this case matter is absolutely hid from view by matter, and the moment of disappearance can be distinctly perceived. But in the case of the moon, which is eclipsed by entering the shadow of the earth, the deprivation of light is gradual; so that it is hardly possible to note, with astronomical exactness, the instant at which the disappearance of the planet's edge takes place.

In a lunar eclipse the first thing to be ascertained is the diameter of the earth's shadow at the distance of the moon. Suppose this shadow, that is, its section at the distance of the moon, to be represented by the circle whose centre is c : it is directly opposite to the sun, its centre is on the ecliptic, and moves in the direction of the sun's general motion, or from west to east.

Let cA be the ecliptic, and let Bc be a part of the moon's orbit, with the node at D . It must be remembered that the whole takes place on a very small part of the sphere, so that all the portions of the orbits

which actually come into use may be represented by straight lines. Let the centre of the moon be at E when that of the shadow is at c ; and let the hourly motions of the sun (that is, of the shadow) and of the moon be CF and EG . If then we communicate to the whole system a motion equal and contrary to CF [MOTION], the shadow will be reduced to rest, and the relative motion of the moon with respect to it will remain unaltered. Take EH equal to CF , and contrary in direction; then EL will represent the quantity and direction of the hourly motion of the moon relatively to the shadow at rest. By geometrical construction therefore, M , N , and P may be ascertained, the positions of the moon's centre at the beginning, middle, and end of the eclipse; and EM , EN , and EP , at the rate of EL to an hour, represent the times elapsed between that of the moon being at E and the phenomena in question. Such is the geometrical process: the one employed in practice is algebraical, and takes in several minor circumstances which it is not worth while here to notice.

An eclipse of the moon is a universal phenomenon, since the moon actually loses her light, in whole or in part; while in an eclipse of the sun, the moon hides the sun from one part of the earth, but not from another. The former can only take place when the conjunction (or sameness of longitude) of the moon and earth's shadow, that is, the opposition of the sun and moon, or the full moon, happens when the moon is near her node. [ECLIPSE; SUN; SAROS.] For the phenomena of the occultation of a star by the moon, see OCCULTATION.

By the *harvest-moon* is meant a phenomenon observed in our latitudes at the time of the full moon nearest to the autumnal equinox, when it happens for a few days that the moon, instead of rising fifty-two minutes later every day, rises for several days nearly at the same time. Something of the same sort takes place always when the moon is near her node; but the circumstance is most remarkable when it happens at the time of greatest moonlight. The reason is that the increase of declination (which is most rapid when the moon is near the equator, which she must be when full moon comes nearly at the time of the equinox) compensates the retardation which would otherwise arise from her orbital motion. [SPHERE.] See the treatise above cited, pp. 80, 81.

The discovery of the telescope, and the examination of the moon which followed, soon showed that the planet always turns the same face towards the earth, or very nearly. From hence it immediately follows that the moon must revolve round an axis in the same time as that axis revolves round the earth. If any one should walk round a circle without turning himself round, that is, keeping his face always in the same direction, he would present alternately his front and back to the interior of the circle. But if he desires to turn his face always inwards, he must turn round in the same direction as he walks round. [MOTION, DIRECTION OF.] If the moon moved uniformly round in her orbit, and had a uniform rotation of the same duration, then if her axis were perpendicular to the plane of the orbit, and the spectator were always at the earth's centre, the face of the moon would be always actually the same. None of these suppositions are true.

1. The motion in the orbit is irregular, while the rotation is uniform and exactly the sidereal month: the consequence will be that when the moon is moving quicker than the average, a little of the western side will be coming into view, and a small portion of the eastern side will be disappearing, and *vice versa*. 2. The axis of the moon is not perpendicular to her orbit, but is out of the perpendicular by an angle of $5^{\circ} 8' 49''$; the consequence is, that as she revolves in her orbit, the north and south poles of the moon will alternately become invisible, each during half a revolution. 3. The spectator is in motion round the earth's axis, which will slightly vary the part seen of the moon in the course of the day. These effects are called librations: (1) the libration in longitude, (2) the libration in latitude, (3) the diurnal libration. The second will be elucidated in SEASONS, CHANGE OF, and the third in PRECESSION and NUTATION.

The way in which we know that the face presented is always nearly the same, is by observation of that face, which is varied by numberless spots and streaks. The following cut represents the general appearance of the moon at full, being a view of its average face in the mean state of libration, that is to say, no part of the present edge is ever hidden by libration without as much of the opposite edge being hidden at some other time.

It may here be mentioned that photography has been applied to the production of views of the lunar surface with great success. Among these, the beautiful photographs by Professor Bond in America, and Mr. Warren De La Rue in this country, hold a distinguished place. Indeed the stereoscopic views of the moon in different states by the latter gentleman, leave but little to be done by succeeding photographers, their effect being such as to excite the surprise and admiration of all by whom they are viewed.

For particulars respecting the spots on the moon, the reader is referred to a work lately published by the Rev. T. W. Webb, entitled 'Celestial Objects for Common Telescopes.' In this little work, which contains a vast amount of information on practical subjects, a map of the moon is given, exhibiting the places and delineations of 404 of the principal craters and other appearances on the lunar surface carefully reduced from the large map published by Beer and Mädler, and verified for the most part by actual observation.

Casual observers of the lunar surface must however bear in mind,

that the figure of a spot varies exceedingly according to the degree of its illumination. Thus many spots and appearances that are strongly marked in the increasing or waning moon are almost if not entirely invisible at the time of full moon. They also vary greatly at

different periods of the lunation, and the alteration in some is so great that they are with difficulty recognised as the same spots. Many astronomers are consequently at the present time engaged in following and delineating the appearance of certain spots through the whole

period of a lunation, and thus it is hoped future observers may be enabled to verify them at any time during that period. This if fully carried out would be a most valuable boon to persons engaged in lunar investigations, as every variation arising from the before-mentioned causes would be readily recognised; and should any actual alteration take place in any of these craters, a thing that has repeatedly been suspected, it could not fail in being immediately detected.

The names of the spots were first given by Riccioli, and his nomenclature is still generally followed, although with very numerous additions. The spots are distinguished by the names of eminent astronomers, philosophers, and mathematicians, both ancient and modern, as Eratosthenes, Plato, Pythagoras, Archimedes, Tycho, Copernicus, Kepler, &c. Many of these spots deserve a more particular notice. Thus Tycho, the large crater in the centre of the lower part of the cut, is remarkable, not only on account of its brilliancy and size, (being 54 miles in diameter, and in depth 16,600 feet,) but also for the radiating streaks, which proceed from it in all directions, some of which extend into the opposite hemisphere. Copernicus, a conspicuous spot to the left of the cut, and about half way to the top, presents an immense crater, 56 miles in diameter, in the centre of which is a mountain having six peaks, of which two are very conspicuous. It is surrounded by a ring composed of successive terraces, ending in a narrow ridge, and rising to the height of 11,000 feet from the bottom of the crater. Aristarchus, the spot still more to the left above Copernicus, is the brightest crater in the moon; it is so brilliant as to be quite dazzling in a large telescope. It is this spot that was supposed by Sir William Herschel to be a volcano in eruption. Plato, a large dark oval spot in the upper portion of the cut, is

remarkable for having the bottom of the crater striped, which is also the case with Archimedes, a large oval spot at no great distance from Plato, in which seven nearly parallel stripes may be easily distinguished. Near Plato is a remarkable insulated pyramidal mountain or rock called Pico, rising from a narrow base to about 7000 feet above the surrounding plain, from which it must present a most magnificent appearance. Eratosthenes, a crater situated near a ridge of lofty mountains called the Apennines, is also a very brilliant object, and Stadius, a neighbouring crater, is one of those to be seen only under peculiar illumination, being absolutely invisible at the time of full moon.

The surface of the moon exhibits a very large number of mountains "almost universally of an exactly circular or cusp shaped form, foreshortened however into ellipses near the limb; but the larger have for the most part flat bottoms within, from which rises centrally a small, steep, conical hill. They offer in short, in its highest perfection, the true volcanic character, as it may be seen in the crater of Vesuvius. . . . And in some of the principal ones, decided marks of volcanic stratification, arising from successive deposits of ejected matter, may be clearly traced with powerful telescopes. What is moreover extremely singular in the geology of the moon is, that although nothing having the character of seas can be traced (for the dusky spots which are commonly called seas, when closely examined, present appearances incompatible with the supposition of deep water) yet there are large regions perfectly level, and apparently of a decided alluvial character." (Sir J. Herschel, 'Astronomy,' p. 229.) The mountains are known by their shadows, which are perfectly visible, and which are long when they are near the boundary of light and darkness, or when the sun is

in the horizon, and disappear when they are 90° from that boundary, or when the sun is overhead. We copy from Schroeter's 'Selenotopographische Fragmente' two representations of the spot Archimedes, the first when very near the dusk part, the second when far from it.

By the help of these shadows, as well by other means, the heights of many of the lunar mountains have been measured, and some have been found whose heights exceed a mile and a half.

From the manner in which the moon is seen, as well as from the stars, when she approaches near them, undergoing no refraction whatever, it is certain that she has either no atmosphere, or one of a degree of tenuity which must exceed, perhaps, that of the best exhausted receiver. From this it has been inferred that there are no fluids at the surface of the moon, since, if there were, an atmosphere must be formed by evaporation. It is however enough to say that the fluids, if such there be, must be very different from those which abound at the surface of the earth. Since the moon has a day (with reference to the sun) of a whole sidereal month in duration, each part is $14\frac{1}{2}$ days in sunlight, and $14\frac{1}{2}$ days without it. The intense heat and cold which must thus alternate would destroy human life, even on the supposition that terrestrial vegetation could be maintained. The fluid on the warm side (if any) must be constantly evaporating and passing off to the colder side. "The consequence must be absolute aridity below the vertical sun, constant accretion of hoar frost in the opposite region, and perhaps a narrow zone of running water at the borders of the enlightened hemisphere. It is possible, then, that evaporation on the one hand, and condensation on the other, may, to a certain extent, preserve an equilibrium of temperature, and mitigate the extreme severity of both climates." (Sir J. Herschel, 'Astronomy,' p. 230.)

The mass of the moon, as determined from her effect upon the earth's motion, is about one-eightieth (or .01252) of that of the earth, her volume is one forty-ninth of that of the earth, and the average density of her material .615, or about six-tenths, of that of the earth. A body weighing six pounds at the earth, would weigh one pound at the moon, if tried against weights which retained their terrestrial gravity. Travelling 10 miles an hour on the surface of the moon would enable a person to keep up with the sun; so that it is not at all impossible that animal life may be maintained by constant migration, keeping always near the boundary of light and darkness.

It might be supposed that nothing could ever be known of the figure of the moon, since we can only see one side. But this very circumstance leads us to some knowledge on the point. It is impossible to believe that the moon should revolve on her axis precisely in the same average time as she revolves round the earth, without half a second of difference, and not to suppose that there is some mechanical connection between the two revolutions, so that either one is a consequence of the other, or both are consequences of some common cause. As this subject is rarely elucidated in elementary treatises, we have somewhat abridged several of those topics which are usually treated, in order to supply considerations for which we could only refer to treatises of the most mathematical character.

It is well known in mechanics that the rotation of a body is in no way affected, if we suppose its centre of gravity to be fixed instead of moveable, provided the same forces act in both cases. Thus if a stick be tossed into the air (or rather into vacuum) by an impulse communicated to a similar stick which revolves on its centre of gravity, the first in its combined rotation and translation, and the second in its rotation only, will always remain parallel to each other, if they were so at first. Let us now suppose a needle placed on a point, and magnetic, round which a ball of iron revolves from A. If the needle be

first at rest, then when the ball moves towards B, it will endeavour to draw the needle towards the position O N, and the needle will begin to revolve in the same direction as the ball. Suppose that by the time the needle points to O N, the ball is at O C, O C and O N being perpendicular; the ball then acts equally on both sides of the needle, and all acceleration of the rotation stops. When the ball arrives at D, it is

tending to destroy its former effect, pulling the end P towards it. It may thus be seen that if the needle were heavy enough, the ball would by its motion cause an oscillation, working to produce rotation in one direction during half its revolution, or rather more, and the opposite effect during rather more than another half revolution, in alternate quarters. But if the needle were light enough, it is easily seen that the rotation in the first direction might be produced so rapidly, that the second mode of action should never be exerted, or the revolving ball should never so far outstrip the needle that N O C should become a right angle. In this case the action would go on in one direction until the needle would acquire a rotation equal to and even exceeding that of the ball. But in the latter case, when the needle overtakes and passes the ball, the opposite action would be immediately exerted, and the acceleration of rotation would be checked. The end would be, that the needle would acquire a rotation equal to that of the ball, on the average, and would revolve so as always to present its point either to the ball, or alternately a little on one side and on the other. The same effect would be produced if the needle, at the commencement, had a rotation nearly equal to that of the ball; the consequence would be, that the action in one direction would continue long enough to establish permanent equality of the average rotations. Without supposing the moon a long needle, with one end turned towards the earth, it is found by calculation, that it is sufficient to suppose it slightly spheroidal, with the longer axis towards the earth. The same mathematical considerations which have so completely resolved the orbital motions, show that the figure of the moon must be an ellipsoid [SURFACES OF THE SECOND DEGREE] revolving round the shorter axis, and presenting the extremity of the longer axis to the earth. But the proportions of these axes have not been well determined, from want of observations: theory has outrun practice on this point. It is but comparatively lately that even the inclination of the moon's equator to the ecliptic has been determined at $1^\circ 30' 10'' 8$; that of the equator to the orbit being $5^\circ 8' 49''$, as already noticed.

One more very curious phenomenon has been shown to be of the same kind as the preceding; namely, of the sort which must be made absolutely true by the earth's attraction, if it were nearly true at the beginning. The moon's equator cuts her orbit in a line which is always parallel, or very nearly so, to the mean position, for the time being, of the line of nodes of the moon's orbit. If the axis of the moon's rotation were perpendicular to the ecliptic, this must be the case, for the moon's equator and the ecliptic would then be parallel planes. And the moon's axis being nearly perpendicular to the ecliptic, it may be shown from spherical trigonometry that the two lines in question could not make an angle of many degrees. But the fact observed (by Dominic Cassini, before the theory of gravitation was thought of) is either actual parallelism, or something differing from it by very trivial oscillations. It is difficult to represent this phenomenon to a person unacquainted with geometry. It may be thus stated: the moon's orbit, the ecliptic, and the moon's equator, are three planes which form a triangular prism when produced. Or thus: if the moon were made to revolve rapidly round its axis, and if the earth were made a source of light and heat giving seasons to the moon, as the sun does to the earth, then the nodes of the moon's orbit on the ecliptic would coincide with the equinoxes, and the moon's orbit would be divided into summer and winter paths by the same line as that in which the sun's path cuts the orbit.

A great many miscellaneous phenomena connected with the moon might be collected, for which we have not space. For the light thrown on her surface when eclipsed see REFRACTION; for a remarkable appearance sometimes observed when she passes over a star see OCCULTATION; for her use in finding LONGITUDE see that word.

MOON, ECLIPSE OF THE. [MOON.]

MOON, SUPERSTITIONS RESPECTING THE. Brand, in his 'Popular Antiquities,' gives a long list of lunar superstitions. It was formerly conceived that if hogs were killed when the moon was increasing, the bacon would prove the better in boiling. (See the *Husbandman's Practice, or Prognostication for Ever*, 8vo., Lond., 1664.)

Tusser, in his 'Five Hundred Points of Husbandry,' under February, says:—

"Sowe peason and beans in the wane of the moon,
Who soweth them sooner, he soweth too soon;
That they with the planet may rest and rise,
And flourish with bearing most plentiful wise."

In Decker's 'Match me in London,' act i., the king says, "My lord, doe you see this change i' th' moone? Sharp hornes do threaten windy weather."

Werenfels, in his 'Dissertation upon Superstition' (Transl., 8vo., Lond., 1748), p. 6, speaking of a superstitious man, says, "He will not commit his seed to the earth when the soil, but when the moon requires it. He will have his hair cut when the moon is either in Leo, that his locks may stare like the lion's shag; or in Aries, that they may curl like a ram's horn. Whatever he would have to grow, he sets about it when she is in her increase; but for what he would have made less, he chuses her wane. When the moon is in Taurus, he never can be persuaded to take physic, lest that animal, which chews its cud, should make him cast it up again. If at any time he has a mind to be

admitted into the presence of a prince, he will wait till the moon is in conjunction with the sun, for 'tis then the society of an inferior with a superior is salutary and successful."

Aubrey, in his 'Miscellanies,' says, "At the first appearance of the new moon after New Year's Day (some say any other new moon is as good), go out in the evening and stand over the spars of a gate or stile, looking on the moon, and say—

All hail to thee, moon, all hail to thee,
I prithee, good moon, reveal to me
This night who my husband (wife) shall be.

You must presently after go to bed. I knew two gentlewomen that did this when they were young maids, and they had dreams of those that married them." Dr. Jamieson has quoted these words as used in Scotland, in a different form.

Tacitus, in his 'Manners of the Ancient Germans,' observes that "they hold their meetings on certain days, either at the new or full moon; for they consider these the most favourable times for entering on any business."

Brand quotes Duchesne's 'History of England,' p. 18, where, speaking of the Irish, he says, "Quand ils voyent la nouvelle lune, ils fléchissent les genoux et récitent l'Oraison Dominicale, à la fin de laquelle ils disent à haute voix, adressant leur parole vers elle, 'Laisse nous aussi sains que tu nous as trouvés;' " which Vallancey confirms in his 'Collectanea de Rebus Hibernicis,' No. xiii., p. 91. "The vulgar Irish at this day retain an adoration to the new moon, crossing themselves, and saying 'May thou leave us as safe as thou hast found us.'" Park observed a similar practice in the interior of Africa among the Mandingoes.

The *Man in the Moon*, one of the most ancient and most popular of our superstitions, is supposed to have originated in the account given in the Book of Numbers, chap. xv., v. 32, &c., of a man who was punished with death for gathering sticks on the Sabbath-day. From allusions by Dante it would seem that the Italians in his day fancied that the man in the moon was Cain with a bundle of thorns (see the 'Inferno' xx, 125-6; Par. ii.) Most nations have their traditions on this subject; Grimm in his 'Deutsche Myth,' has collected a great many.

MOOR, a name given to extensive wastes which are covered with heath, and the soil of which consists of poor light earth, mixed generally with a considerable portion of peat. The want of fertility in moors arises chiefly from a deficiency or superabundance of moisture, the subsoil being either too porous to retain it, or too impervious to allow it to escape. Both extremes occur in some moors, which are parched up in dry weather, and converted into a dark mud by any continuance of rain. A considerable portion of iron in a state of hydrate is also generally found in the soil of moors, which is very hurtful to the vegetation of plants, except heath, furze, and other coarse plants, which almost entirely cover the moors. This iron is carried down through the light surface-soil, and, if it meets with a less porous earth below, is frequently deposited in a thin layer, cementing the particles of silicious sand, which are carried down with it, and forming what is called the *heath-pan* or *moor-band*. This substance is perfectly impervious to water, and wherever it exists in a continuous state, all attempts at improvement are vain, till it is broken through or removed. The roots of trees occasionally find a passage through interstices or fractures of the pan, and then often grow luxuriantly. But wherever young trees are planted, without the precaution of breaking through the moor-band, they invariably fail, and disappoint the expectations of the planter, who, seeing fine large trees growing around, naturally imagined that the soil was peculiarly fitted for them. If the stump of a large tree, which has been cut down, is grubbed up, pieces of the moor-band may often be seen all around the stem, at a short depth below the surface, so arranged as to show evidently that the tap-root, having found an aperture, and extending its fibres downwards into a better soil, has, in swelling, broken the pan and pushed it aside. When the moor consists of a loose peaty earth of little depth incumbent on a rock, as is the case in many mountainous countries, no art can fertilise it. In dry weather the whole surface has the appearance of a brown powder like snuff, which becomes a spongy peat as soon as it is soaked with rain. The hardest heaths and mosses alone can bear this alternation; and where the substratum of rock is not broken into crevices through which the roots penetrate, all vegetation ceases except mosses and lichens.

In the valleys, where the waters have brought various earths mixed with decayed vegetable matter from the surrounding hills, the substance deposited is mostly peat, which is useful as fuel in proportion to the quantity of bitumen and carbon which it contains. When the peaty matter is mixed with a considerable portion of clay and sand, forming a peaty loam, and a convenient outlet can be found for the superabundant water, it is very capable of improvement, chiefly by draining, burning, and liming. [BARREN LAND.] As soon as the heath is destroyed by burning it together with a portion of the surface, and the peat-bog has acquired a certain consistency by draining, the application of lime will enable it to produce potatoes and oats, and the peaty matter will soon be converted into a rich soil, abounding in humus, and requiring only repeated cultivation to become extremely fertile. [PEAT.] Much judgment is required to know whether a con-

siderable capital may be safely laid out in the improvement of moors. In some cases the return is certain and very considerable; in others the capital is entirely thrown away. Sometimes extensive moors have been converted into flourishing farms of arable and grass land, as in many parts of Scotland and the north of England; sometimes they have been most advantageously planted with forest-trees, and, where there is a great extent of waste and a scanty population, this is generally the most certain mode of improving a property, although the return is slow and distant.

A prudent proprietor, before he begins expensive improvements, will do well to have his wastes carefully examined. The soil and subsoil, and the situation of the springs, should be carefully ascertained by boring in different places to the depth of five or six feet. It will thus appear whether any portion can be readily converted into arable land, or improved as pasture, or whether plantations of trees may be safely made. The division of the waste into fields by deep ditches will often be sufficient to lay them dry; if not, recourse must be had to draining. In the humid climate of Great Britain and Ireland, the water which falls in rains in the winter half of the year is always more than is necessary for healthy vegetation, and ditches are generally indispensable to keep the surface dry. The convenience of enclosures for pasturing cattle and sheep to advantage, added to this, has made the division of wastes by ditches and banks an invariable preliminary to cultivation. Expensive draining may not always be expedient, where the soil is naturally poor; but wherever there is sufficient loam, either immediately under the peat or mixed with it, and lime can be obtained at a moderate cost, the soil may always be brought into cultivation, and will fully repay any judicious outlay of capital.

In many situations on the slopes of hills, or in the valleys, good earth may be found at a moderate depth, which, being carted on the moor, will materially improve the surface. It should be carted out in the beginning of winter, and spread over the surface an inch or two deep. It should be left so a considerable time, especially if there is any appearance of ochre or iron in the earth. The exposure to the air and rain will convert the hydrate or carbonate of iron into an oxide, and thus render it innocuous. The earth also will absorb fertilising portions of the atmosphere, and be much improved. It may then be ploughed in with a shallow furrow, and incorporated with the natural soil by harrowing. A small quantity of lime and manure will bring this mixture into a productive state.

There are many moors which, although incapable of profitable improvement as arable land, may, at a comparatively small expense, be much improved as pasture for sheep and cattle. The principal means of effecting this are, judicious draining by ditches, and enclosing the fields with banks or stone walls, both as shelter for the stock and for convenience of feeding. The heath may be burnt and the ashes spread about, and the surface having been scarified to the depth of a few inches, some grass-seeds suited to the soil and climate may be sown. The surface will soon show a manifest change by the increase of green patches, and a subsequent liming will complete the improvement. When the health of the stock, as well as the increase of food, is taken into the account, it will be found that such an improvement of moorland soon repays the outlay.

When the surface of the ground is very uneven with protruding rocks, interspersed with large stones, the only improvement which can be undertaken is to plant trees, chiefly of the fir or pine tribe, which will grow well if put in judiciously. The plants should be of the last year only, and the ground where they are to be planted should be well examined to find out whether there is a moor-band or rock below. The first must be broken through, which may be done by trenching or by means of heavy-pointed iron bars thrust into the ground with considerable force, wherever a plant is put in. If there is a rock below with six inches of earth over it, provided it be not of a very compact and solid nature, the fir-trees will grow rapidly, and the roots will find crevices to strike into. A plantation should begin in a sheltered spot, and it may be enlarged every year towards the more exposed side. Thus even the highest and bleakest hills may in time be covered with wood, and, if properly managed, cannot fail to be profitable. [PLANTATIONS.]

Moss-land is often confounded with moor; but is very distinct in its nature. Moss-land is produced by the accumulation of aquatic plants, and its origin is chiefly vegetable. When it has a considerable depth, and its substance has lost all power of vegetation, it forms peat-bogs of more or less consistency, as the water is drained off or retained in its pores. In the latter case it appears like a spongy vegetable mass, consisting almost entirely of fibres, so interwoven as to form a very light substance, in which water is easily retained, which keeps up a kind of internal vegetation, by which the quantity of the moss is gradually increased. This is the substance which covers the surface of bogs, and where it is of some consistence it allows a passage over them [Bog]; but where it is very thin and loose it deceives the eye by an appearance of solidity, like that of a smooth green pasture, which, however, gives way to the pressure of the foot, and allows it to sink through it with very little resistance. The only way to improve moss is to drain it, and then convert the vegetable matter of which it is composed into soil, by means of lime and pressure. The latter is effected by putting on a considerable quantity of earth, especially sand and gravel, which, incorporating with the moss, consolidates it, and

assists the lime in decomposing the vegetable fibre. After this it becomes extremely fertile, producing abundant crops of potatoes and oats; and whenever it has acquired sufficient solidity by the treading of sheep and cattle, it will produce good crops of wheat, or, if laid down to grass, give abundance of hay and pasture. Trees do not thrive in mossy soil, there being too little solidity for the roots, and the large trunks which are frequently found in bogs must have grown before the moss was formed. This may be easily imagined. A wood laid flat by a storm or hurricane may obstruct the natural flow of the waters, and cause them to accumulate. The prostrate trees become surrounded by aquatic plants, which spread their fibres and roots freely through the water, and, decaying, make room for others. Thus the trees are gradually covered and buried in the moss till future generations find them when the moss or bog is explored for fuel or for improvement. The trees which are found buried in mosses frequently show evident signs of having been gradually covered. The upper surface is often decayed and uneven, while the lower shows that it has remained submerged and protected from the contact and influence of the air, and thus preserved from rotting.

MOORISH ARCHITECTURE. [SARACENIC ARCHITECTURE.]

MORAL SENSE is a name which, occurring first in Lord Shaftesbury's 'Inquiry concerning Virtue,' and afterwards adopted by Hutcheson, has since come to be very generally employed to denote the feelings with which we regard men's actions and dispositions. These feelings are known also by the name of feelings of moral approbation and moral disapprobation. This last name answers every purpose which is sought in naming, and is at the same time free from the many objections that may be urged against the phrase *moral sense*.

The phrase *moral sense* is objectionable, first of all, because the feelings for which it is proposed as a name have no analogy whatever to the external senses, from which the phrase is borrowed. The phrase therefore tends to give a wrong notion of the thing for which it is a name, an objection which is of itself altogether fatal to the use of the phrase for the purpose of naming.

A masterly exposition of the objectionableness of the phrase *moral sense*, and of the theories that are founded upon it, will be found in Mr. Austin's 'Province of Jurisprudence determined.' [MORALS.]

MORALITIES or MORAL PLAYS. [DRAMA.]

MORALS is a word used in several different senses, which it is desirable to distinguish. 1. It has been employed, together with the expressions *moral philosophy* and *moral science*, to denote the whole field of knowledge relating primarily to the mind of man; and in this sense it is co-extensive with the word *metaphysics*. To this use of the word there are many objections; and it has accordingly now almost entirely ceased. 2. *Morals*, as well as the expressions *moral philosophy* and *moral science*, denotes specially the science of what is called man's duty, what he ought and ought not to think, feel, say, do. In this sense of the word, morals is one department of metaphysics; mental philosophy, or mental science, or psychology (which, as we shall see presently, is a necessary foundation for morals), being another department. This is in every way the most convenient use of the word, and is now generally sanctioned by custom. In this sense of the word *morals*, it is convertible with *ethics* and with *deontology*, a word coined by Mr. Bentham. 3. *Morals* and *ethics* are at the same time names for the art corresponding to the science which has just been spoken of, the art of performing one's duty, or (as it is generally described) the art of living a good and a happy life. The art and the science being coextensive, and differing only in this, that the same subject-matter is viewed from different points, the indiscriminate application of the same term to both engenders no confusion worthy of notice. 4. *Morals* is, in current conversation, synonymous with *morality*; thus denoting not only the science and the art, but also what is the subject-matter both of the one and of the other.

It is the purpose of this article to give a brief general account of morals, considered as the science of man's duty.

Morals then is a name for the science which teaches what it is man's duty to do and not to do, or (changing the phrase) what he ought and ought not to do; or again, what it is respectively right and wrong for him to do; or (to resort to yet another change of phrase) which teaches what is respectively virtue and vice. Our account of the science must necessarily commence with an explanation of this, its fundamental idea, which is thus expressed in so many different ways.

It is man's duty to do, or he ought to do, or it is right that he should do, or lastly, that is virtue, which, on the most general view possible of the tendencies of a disposition or an action, conduces most to the happiness of mankind. That which of any two acts thus viewed, conduces the less to this happiness, it is his duty not to do; or he ought not to do, or it is wrong for him to do, or lastly is vice. So, absolutely and unconditionally, of any disposition or action which tends, on the whole, to cause unhappiness. It is generally stated, in consistency with this explanation, that conduciveness to the general happiness of mankind is the criterion of duty or virtue.

Two questions now arise, to which, before we proceed further, some sort of answer must be given. The answers to these questions will lead us to separate the science of morals from two other sciences with which it is often more or less confounded, namely, mental science,

or psychology, and theology, and also to point out the relations in which it stands to these sciences. The two questions are,—what does human happiness consist of? and what renders the pursuit of human happiness man's duty?

We shall answer the second of these questions first. It is man's duty to strive to increase the general amount of human happiness, because he knows, both from the adaptation of the external world to that end, and from express revelation of God's will, that God desires the happiness of mankind. The full and detailed establishment of this proposition belongs to theology, in its two departments of natural and revealed religion. Thus is morals connected with theology. We have said that their provinces have been often more or less confounded, and this has taken place principally in two ways. God having revealed, in a general manner, the assignment of rewards and punishments in a future life to the performance of duty and its violation in this, some writers, as Paley for instance (who defines virtue as "the doing good to mankind in obedience to the will of God, and for the sake of everlasting happiness"), have directly referred virtue to an expectation of these rewards and punishments, and, instead of treating them as something extraneous and accidental, have introduced them as essentials into the definition of morality. Now morals has nothing to do with these rewards and punishments further than to determine what are the dispositions and actions to which they are respectively assigned; and this is determined altogether independently of the rewards and punishments themselves. The other way in which the provinces of morals and theology have been confounded (and here the confusion is complete) is by deriving all duty directly from the revealed will of God. Those who consult the Bible only, as being the depository of God's revealed will, for a complete enumeration of their duties, clearly reject morals as an independent science, and merge it entirely in theology. It is needless to observe that the Bible, which, as Mr. Burke observes in a well-known passage, "is not one summary of doctrines regularly digested, in which a man could not mistake his way," cannot take the place of, any more than it can be superseded by, a science which systematically treats duty on the principle of conduciveness to the general happiness of mankind.

The question, what does human happiness consist of? remains to be answered. And here too we can only generally indicate the mode of answering the question, rather than provide in detail the answer itself. Man is so framed as to be susceptible of certain pleasures and certain pains. These pleasures and pains are of two different kinds, physical and intellectual; in the last division being included the pleasures and pains of sympathy, and also those derived from the feelings of moral approbation and disapprobation. These pleasures and pains differ of course among themselves, both in kind and degree. Now generally the greater the number of pleasures gratified, and the greater the number of pains avoided, the more is man's happiness consulted; and when there is a necessity of choice between pleasures and pains of different kinds, this happiness is consulted more, in proportion as the pleasures and pains respectively gratified and avoided are more enduring and extensive in effect. The full enumeration and explanation of all the pleasures and pains of which man is by nature susceptible belongs to psychology, or mental science. Morals, availing itself of the results of this science, proceeds to determine, by a comparison, in each case, of known pleasures and pains, in respect of number and value, the different duties of man.

Much confusion has been made between mental and moral science, first by treating the moral feelings (as they are called), or the feelings of moral approbation and disapprobation, as the immediate object of moral science; and secondly, by supposing these feelings, under such names as conscience and moral sense, to be the only and all-sufficient criterion of morality or duty. The consideration of these feelings, as of all other feelings, belongs to mental science. So far as they contribute to increase the number of human pleasures and pains, their consideration is a necessary preliminary to the treatment of moral science. So far, on the other hand, as the proper direction of these feelings is concerned (which belongs to the act of education), it is clear that the enumeration and explanation of duties should precede. Those writers who, merging altogether moral in mental science, derive all duties from what they call an independent moral faculty, which, by way of making the thing clearer, they name *conscience*, or *moral sense*, or *right reason*, commit the error of mistaking the effect for the cause. So far as the judgments of this conscience, or moral sense, or right reason, are good and proper judgments, so far must they be founded upon the results of moral science, treated, as we propose to treat it, in reference to the principle of conduciveness to the happiness of mankind. And it will invariably be found that whatever of good exists in any moral system professing to be founded on something else is really (though its authors imagine otherwise) derived from this science. But where direct and conscious reference is not made to this science, there is no longer any security for the proper direction of the moral feelings. As Dr. Paley happily expresses it, "a system of morality, built upon instincts, will only find out reasons and excuses for opinions and practices already established—will seldom correct or reform either."

Thus much in the way of preliminary disquisition. We now proceed to enumerate man's several duties.

It is of course out of the question to give a complete enumeration of

single separate duties, or (in other words) to state in detail all that a man ought or ought not to do under all possible varieties of circumstances. This can hardly be expected, or at any rate is seldom professed, and never accomplished, in treatises expressly devoted to the subject. The most at all events that can be done here is to name, with the addition of some brief general explanation, the chief general classes of duties. The adaptation of these general duties to particular cases is often obvious. In some cases, which will be specially noticed, the carrying out into minute detail of general rules of duty opens new and large departments of inquiry, which may be considered either as constituting separate sciences, or as belonging to other sciences rather than to morals.

In thus taking refuge in a general classification of duties, we shall have to furnish the reader with a list of *dispositions* which it is the duty of man respectively to cultivate and not to cultivate. A disposition is a tendency in a man to act (under which word is comprehended thinking, feeling, speaking, and doing) generally in a certain way. The names for the different dispositions thus come to embrace general classes of actions. For instance, the disposition called *benevolence* leads to innumerable actions which, under innumerable different circumstances, it is man's duty to perform; and the name therefore stands as a general name for all these actions. To name singly and separately all these actions would perhaps not be practicable, and is certainly not desirable. Certain sub-classes of them may be named, in explaining the beneficial tendency of the general disposition, or (in other words) the reasons why it is man's duty to cultivate this disposition. This last explanation will necessarily comprehend a general view of the advantages of the different actions which the disposition tends to produce.

There are many different principles of classification on which the enumeration of duties may proceed. It is perhaps not too much to say that all duties may be deduced, with a greater or less exercise of ingenuity, as corollaries from any one which has been previously established. Thus Wollaston, in his 'Religion of Nature,' deduces all man's duties from the duty of truth. Hobbes again, in his 'De Cive,' derives all morality from the duty of preserving peace. It is clear that the mode to be adopted of treating the subject, or, in other words, the mode of classifying our enumeration of duties, is a matter entirely of convenience; and, merely as a matter of convenience, we shall adopt the division of duties which has been partly acted upon by Dr. Paley, and which is perhaps the division most generally resorted to by writers on morals.

We shall treat of a man's duties, first, as they regard himself individually, and, secondly, as they regard others. It is necessary to remark, in order to prevent misapprehension, that one duty is a duty towards oneself, and another duty is a duty towards others, not on account of its tending respectively to produce happiness only to oneself or only to others, but simply from the accidental circumstance of oneself in the one case and others in the other being, as it were, the outward object of the action or disposition which constitutes the duty. "Those acts of ours," to quote from Mr. James Mill, "which are primarily useful to ourselves, are secondarily useful to others; and those which are primarily useful to others are secondarily useful to ourselves." ('Analysis of the Human Mind,' vol. ii., p. 234.) Much of the good resulting from the performance of what we call duties towards ourselves consists in our being thereby better enabled to do good to others; and together with the happiness conferred on others by the performance of our duties towards them, is the happiness caused to ourselves by the gratification of our feelings of sympathy and of duty, and the additional security that is gained for the good-will of others towards ourselves.

I. A man's duty to himself consists generally in the preservation of the life with which his Creator has endowed him, and in the improvement, to the greatest degree in his power, of the faculties which he possesses.

The first part of this duty is altogether negative. A man must abstain from wantonly exposing himself to danger, or, in other words, he must be *prudent*, and he must refrain from *suicide*. For when man learns that God has adapted his created world to the production of general happiness, he learns at the same time that life has been given for that purpose; and in foolishly risking or in laying violent hands upon his own life, he tends so far to mar God's object. He throws away his own means of attaining happiness in the way in which God has willed that he should attain it, and he destroys also his means of promoting the happiness of others.

As regards the second part of a man's duty towards himself, consisting in the improvement of his faculties, or, as we may otherwise express it, of his intellectual and moral being, this is partly positive and partly negative. It is a man's duty to improve himself, so far as he can, by study and by cultivating good dispositions; the full explanation of the best mode of doing which belongs properly to the subject of education. It is his duty also not to deteriorate his character by sensual excesses. The vices which he has thus to guard against are principally two, *lust* and *intemperance*; the latter of which divides itself into *drunkenness* and *gluttony*. The names of the two virtues opposite to the two vices of lust and intemperance are *chastity* and *temperance*. The cultivation of these two virtues, or the abstinence from the two corresponding vices, is recommended not only by the

good accruing to the individual, but also by the extent to which he is thereby saved from inflicting injury on others.

II. In considering a man's duties towards others, we would adopt the subdivision of duties towards men generally as men, and duties towards men as members of the same society. These last duties will be again subdivided into duties towards members of the same political society or state, and duties towards members of the same family.

1. The duties towards men generally as men, or towards mankind, may be comprehended under the general names of *benevolence* or *kindness*, *courage*, *sincerity*, and *humility*.

In benevolence or kindness are included *sympathy*, or a general disposition to assist our fellow-men; *pity*, or kindness towards those in distress, and towards inferiors; *generosity* or *liberality*, which, being the disposition to make our own means serviceable to others, turns pity to good account; *gratitude*; and *charity*, in the sense in which it is used by St. Paul, or the disposition to judge kindly of others' conduct. The vices opposed to sympathy, pity, generosity, gratitude, and charity, are *selfishness*, *hardheartedness* or *cruelty*, *avarice*, *ingratitude*, and *malevolence* or *uncharitableness*. *Slander* is one principal form in which the last-mentioned evil disposition displays itself. The cultivation of the virtues comprehended under the name *benevolence*, and the avoidance of the opposite vices, have an obvious and immediate bearing on the happiness of others. At the same time it is not to be forgotten that happiness accrues to the benevolent man himself from the gratification of his natural feelings of sympathy, and that by doing good to others he disposes others to do good to him.

Courage is valuable, as tending to give effect to our benevolence. It must not exist in such excess as to lead a man to adventure a great risk for a disproportionately small object, and must therefore be governed by prudence. Mr. Mill indeed has treated of courage as a particular form of prudence, a mode of treating of it which we cannot think proper. There is an obvious difference, which Mr. Mill seems strangely to have lost sight of, between courage being governed by prudence, as it unquestionably ought to be, and courage being only a particular form of prudence.

Sincerity comprehends *truth* in words and *honesty* or *justice* in conduct. The manner in which the practice of these virtues, or the abstinence from the opposite vices of *lying* and *cheating*, is recommended by general utility, is obvious. Without the general observance of truth and honesty, men would have no confidence in one another, and there would be no safety. The proverb, that "honesty is the best policy," pithily expresses the bearing of this virtue on one's own good. Kant, in his 'Metaphysic of Ethics' (*Metaphysik der Sitten*), classes the virtue of sincerity among the duties owed by a man to himself. "A lie is the abandonment and, as it were, the annihilation of the dignity of a man."

It remains to speak of *humility*. This is perhaps not so decidedly a virtue as its opposite, *pride*, is a vice. The evil of this vice consists in its tendency to hurt the feelings of others, and to diminish our disposition to do good. Tolerance of others' opinions, and reverence towards superiors in intellectual and moral worth, are forms of humility; and these are dispositions which, when they exist, are fruitful of much good both for oneself and for others.

2. The duties towards men as members of the same political society or state, resolve themselves into the general dispositions of *patriotism* and *obedience*. The first is a virtue, the value of which has been often greatly overrated, and which is very apt to degenerate into the failing called *nationality*. But nevertheless it is a virtue. As the general happiness is best pursued by each individual making his own happiness his own chief object, and again by each body of individuals making the pursuit of their own separate interests their chief object, patriotism properly tempered, or the desire to benefit one's own country so long as this is not done in such manner as to injure other countries, is one valuable means of promoting the general happiness of mankind. Of obedience to those who are invested with authority in a state, and to the laws, it belongs to morals to speak only in the most general manner. The filling up of the detail belongs to political science. This science having determined what laws ought to be enacted, on the ground of conduciveness to general happiness, morals enjoins obedience to them, without reference to their individual goodness, but for the sake of maintaining political society generally, and of preserving to men all the advantages which political society yields.

3. The duties towards others who are members of the same family consist altogether in affection, which manifests itself differently according to the different family relations. Thus we speak of conjugal affection, paternal and maternal affection, filial affection, and fraternal affection. Conjugal affection implies fidelity. The proper exercise of the paternal and maternal affection opens a wide field of discussion; but it may be said generally to show itself best in the proper education of the children. Into filial affection gratitude and reverence largely enter. Fraternal affection differs from friendship only in the peculiar relation under which the feeling exists.

Thus have we given a brief general summary of man's duties. We have said nothing of duties towards God, which are generally made to form a separate division in treatises on morals, because we conceive that these duties, so far as they depend on God's special commands, and thus differ from the duties which we have enumerated, and which we come to know by observing their tendency to promote general

happiness, belong to the separate subject of religion; in the same way as the duties which depend on positive laws enacted in a political society have been referred to political science. Generally we may say that man ought to entertain feelings of reverence and gratitude to God, by reason of his superiority, and of the blessings which he has conferred upon us. But the duty of entertaining these feelings in this particular case flows at once from the general duties of gratitude to a benefactor and reverence towards a superior; and inasmuch as the application of the general duties to this particular case needs not the assistance of revelation, and involves no essential difference from the application to other cases, there seems no necessity for a separate division.

So also the duty of kindness to the inferior animals must be taken as a corollary from the general duty of kindness which has been inculcated. The pain which we believe that God wills shall not be inflicted upon men, we must believe too that he wills shall not be inflicted on other animals which he has created. The pain of which animals are susceptible we suppose to be of the same sort as that of which men are susceptible; at least we have no means of conceiving any other sort of pain. And inasmuch as no different circumstances are introduced, there is no need for a separate division wherein to treat of our duties towards the inferior animals.

MORASS. [MARSHES.]

MORAVIANS, or MORAVIAN BRETHREN, a congregation of Christians descended from the Bohemian brethren, who were a branch of the Hussites. [HUSS, JOHN, in BIOG. DIV.] The Bohemian brethren dissented from the Callixtines, and refused to subscribe to the articles of agreement between that party and the council of Basel in 1433. They then formed themselves into a distinct community, called "the Brothers' Union," and as they were obliged to live in seclusion through fear of persecution, they were called by their enemies "Grübenheimer" or Troglodytes. They looked upon the Scriptures as their rule of faith, rejected transubstantiation, and were very strict in their discipline, excluding the vicious, the scoffers, and the worldly from their communion. They established among themselves a superintendence over the practical and domestic conduct of individuals, who were distributed into three classes, the beginners, the proficient, and the perfect. They had their bishops, seniors, presbyters, and deacons, who administered their civil as well as ecclesiastical affairs. Like the Quakers they refused to do military service.

When the great Reformation took place in Germany, the Bohemian brethren sent envoys to Luther in 1522, who approved of most of their doctrines and discipline, and although he did not admit every article of their confession of faith, yet he said that it might be tolerated as it was. (Mosheim, 'Ecclesiastical History,' xvi. cent., iii. 2.)

In 1547 most of the brethren were expelled from Bohemia by Ferdinand I., upon which they took refuge in Poland and Prussia, where they formed several settlements, especially at Marienwerder. They were united for a time with the Lutherans by the convention of Sendomir, but afterwards drew closer to the Calvinists at the synods of Ostrorog in 1620 and 1627, and adopted Calvin's creed, retaining their own Bohemian forms of discipline. (Elsner, 'Brevis Conspectus Doctrinæ Fratrum Bohemorum,' in Gerdes's 'Miscellanea Groningiana,' vol. vi.)

Under Maximilian II., those brethren who had remained in Bohemia and Moravia enjoyed full toleration, and they formed their chief settlement at Fulnek in Moravia, whence they received the name of Moravian brethren. But in the subsequent 'Thirty Years' war, their settlements in Bohemia and Moravia were utterly destroyed, and, after various migrations, their descendants were settled, in 1722, by Count Zinzendorf, on his estate of Bethelsdorf in Upper Lusatia, where their colony took the name of Herrnhut, from a hill in the vicinity called Hutsberg. [ZINZENDORF, in BIOG. DIV.] They then established themselves as a new community under the name of the United Brethren, to which Protestants of every denomination were admitted, without being obliged to renounce their respective creeds, but on condition of conforming to their rules of discipline, which were derived from those of the Bohemian brethren. Since that time the community of the United or Moravian brethren has greatly increased, and has spread through Germany, Holland, the United States, and other Protestant countries. Wherever they have formed a new and distinct settlement, they have enforced their regulations of civil and religious discipline upon all the members of the community, but there are many Moravians scattered about in towns among people of different communions, where they form small congregations and have their own meetings. The Moravians do not assume to constitute a separate sect, and whenever they have been required as a body to state their creed, they have professed a general adherence to the confession of Augsburg, and their preachers, without pledging themselves to all its articles, reject any doctrine which is repugnant to it. They avoid discussions on the speculative truths of religion; they acknowledge the manifestation of God in Christ, and consider the life, sufferings, death, and merits of the Saviour as the foundation of their faith. They look upon the Scriptures as the revelation of God. They also believe that the Spirit of God continues to enlighten inwardly those who pray for it for the purpose of regulating their conduct, and they make a practice of invoking it in circumstances of doubt and uncertainty, before coming to a determi-

nation. Each community, represented by its elders, presbyters, and deacons, provides for the spiritual wants of its members, for its churches, schools, hospitals, and other public establishments, and the funds for these objects are raised partly by subscriptions and partly by rates levied on the householders. In other respects every family in the community carries on its private affairs, and manages its own interests and property as in other communities. The erroneous notion of their having community of goods arose from the circumstance that some of their first settlers in North America, being few and forlorn among strangers, found it convenient for a time to put their earnings into a common stock.

One of the principal objects of the Moravian institution which they pursued at a very early period, was to send out missionaries among the heathen. Their mission to Greenland has been celebrated by James Montgomery, and they have furnished missionaries for the Caffres and Betchouanas in South Africa, for the Delaware Indians and the Cherokees in North America, for the Esquimaux of Labrador, and for the negroes of the West Indies.

The Moravians, like the Quakers, reject gaudiness and ornament. Promiscuous assemblages of the two sexes are forbidden among them, as well as plays, games, and dancing. They have however church music and singing. The unmarried men live together in a separate building called the house of single brethren, under the superintendence of an elder; and there are likewise houses for single sisters and widows. Marriages among members of the society must be sanctioned by the elders. They wear no mourning for the dead, looking upon death as a happy release from earthly bonds: their expression on such an event is, that the deceased is gone home to the Lord.

MORDANTS. [DYEING.]

MORIC ACID. [TANNIC ACIDS.]

MORIN. [TANNIC ACIDS.]

MORINDIN ($C_{39}H_{15}O_{15}$). A non-azotised-colouring principle, found in the root of the *Morinda citrifolia*. By the action of heat it yields morindone ($C_{24}H_{10}O_{10}$). M. Rochleder believes that morindin is identical with ruberythric acid, and morindone with alizarin. [MADDER, COLOURING MATTERS OF.]

MORINDONE. [MORINDIN.]

MORINGIC ACID. [BEN, OIL OF.]

MORINTANNIC ACID. [TANNIC ACIDS.]

MOROXYLIC ACID. [TANNIC ACIDS.]

MORPHIA. [OPIUM, ALKALOIDS OF.]

MORPHINE. [OPIUM, ALKALOIDS OF.]

MORRIS DANCE. Douce, in a dissertation on the ancient English Morris Dance at the end of the second volume of his 'Illustrations of Shakspeare,' affirms that both English and foreign glossaries uniformly ascribe the origin of this dance to the Moors; although the genuine Moorish or Morisco dance was, no doubt, very different from the European Morris. Strutt, in his 'Sports and Pastimes of the People of England,' has cited a passage from the play of 'Variety,' 1649, in which the Spanish Morisco is mentioned as being danced by one person only, and he thinks the origin of the term might be found at home. Mr. Douce, however, maintains that this not only shows the legitimacy of the term Morris, but that the real and uncorrupted Moorish dance was to be found in Spain, where it still continues to delight both natives and foreigners under the name of the fandango.

It has been supposed that the Morris dance was first brought to England in the time of Edward III., when John of Gaunt returned from Spain; but it is more probable that we had it from our Gallic neighbours, or even from the Flemings. Few, if any, vestiges of it can be traced before the reign of Henry VII., about which time, and particularly in that of Henry VIII., the churchwardens' accounts of numerous parishes show that the Morris dance made a considerable figure at parochial festivals.

The hobby-horse, which once performed the principal character in the dance, was a light frame of wicker-work, furnished with a paste-board head and neck of a horse. This was buckled round the waist, and covered with a foot-cloth which reached on the ground, and concealed at once the legs of the performer and his gingling apparatus. Thus equipped, he pranced and curvetted in all directions, neighing, and exhibiting specimens of boisterous and burlesque horsemanship. Besides the hobby-horse, there were, the fool or buffoon of the party; May or Maid Marian, and her paramour a friar; a serving-man, a piper, and two Moriscoes. The dress of these personages is described by Fletcher in his 'Women Pleased,' when he says:—

"Where are your bells then,
Your rings, your ribbands, friend, and your clean napkins,
Your nosegay in your hat, pinn'd up?" &c.

Gifford, in his edition of Ben Jonson's works, remarks, "When the right good-will with which these persons capered is taken into consideration, the clean napkin, which was never omitted, will not appear the least necessary part of the apparatus." Thus Clod, in the masque of 'The Gipsies,' observes, "They would be Morris dancers by their gingle, but they have no napkins." Maid Marian was the lady or queen of the May.

MORTALITY, BILLS OF. [BILLS OF MORTALITY.]

MORTALITY, LAW OF. In this article we intend to confine ourselves to some account of our present knowledge, theoretical and

practical, of the laws which are found to regulate mortality among mankind in this country.

Uncertain as is the life of any one individual, it is now very well known that if two different numbers of individuals, at or near the same age, be taken, the number that will be left at the end of a few years will be nearly the same, if they exist during that time under similar circumstances. No tables, however different the station and circumstances of the person from whose lives they are made, differ from one another by anything like the amount which might be supposed likely by one who turns his thoughts rather to the existence of one individual than of a large number. A little consideration will make the probability of something like permanence in the distribution of mortality very great *à priori*. That harvests fluctuate in goodness is very well known; but it is also obvious that if the fluctuations upon a whole country had been as great as those upon an individual field, the human race must long ere this have been starved off the face of the earth. If, in the same manner, the mortality of races had varied as much as that of families, it is impossible that the population of any country could have gone on in a gradual and regulated state of increase; or supposing that large fluctuations had compensated each other, the consequence must have been such a disproportion of the numbers living at different ages as it never has occurred to any one to imagine possible.

The law of mortality, theoretically speaking, is a mathematical relation between the numbers living at different ages: so that, having given a large number of persons alive at one age, it can be deduced by the law what number shall survive any given number of years: practically speaking, it is, in the absence of such a mathematical law, the exhibition in a table of the numbers surviving at the end of each year. Thus, DE MOIVRE'S HYPOTHESIS (namely, the supposition that out of 86 persons born one dies every year till all are extinct) is an asserted theoretical law of mortality; while the Carlisle table, presently given, is a practical one.

If y represent the number of persons living at the age of x , out of a certain number a at a certain previous age (usually the time of birth), then if a line varying with x be made the abscissa of a curve, and another varying with y its ordinate, this curve may be called the curve of mortality. Its form, as deduced from a given set of observations, may lead, by comparison with known curves, to an equation which, more or less accurately, connects y and x .

Besides De Moivre's hypothesis, others have been given, the principal of which we shall notice in order.

A curve following a mathematical law may be drawn through any points, however great their number or irregular their distribution; but the greater the number of points, the more complex will be the equation of the curve. With an equation of a high degree (the tenth, perhaps, or the twelfth), any given table of mortality might be very nearly represented; but such complexity would be useless, and it has therefore never been attempted. Similarly, by using arcs of different curves, a near representation might be attained; but such a method, being practicable in many different ways, would not possess the interest attaching to one simple and uniform law, and would only attract attention by offering facilities for the actual calculation of life-contingencies.

In 1765 Lambert presented an equation of the following form, as representing very closely the London table (e is the base of Napier's logarithms):—

$$y = 10000 \left(\frac{96-x}{96} \right)^2 - 6176 \left\{ e^{-ax} - e^{-\beta x} \right\}$$

a being $= 1 : 13.682$, and $\beta = 1 : 2.43114$, and y being the number surviving at the age of x , out of 10,000 born. This form, if it could be made to represent other tables, by an alteration in the constants, would be one of great practical utility; but we are not aware of any attempt having been made to extend it.

Mr. Benjamin Gompertz, in 1825, presented to the Royal Society a memoir 'On the Nature of the Function expressive of the Law of Human Mortality.' As this ingenious paper contains a deduction from a principle of high probability, and terminates in a conclusion which accords in a great degree with observed facts, it must always be considered as a very remarkable page in the history of the inquiry before us. We enter into some detail of it the more readily, that it is necessary as an act of justice to Mr. Gompertz, whose ideas have been adopted by a writer on the subject, in a work published in 1832, without anything approaching to a sufficient acknowledgment. (See on this point the 'Journal of the Institute of Actuaries,' vol. ix., part 2, July, 1860.)

There is in the human constitution a power of resisting the effects of disease, which increases from birth up to a certain age, and diminishes from that time forwards; the evidence of such diminution being the increased proportion of deaths in a given time. The proportion is found, in most tables, not to be altered by equal quantities in equal times, but to diminish in a greater ratio as life goes on. Mr. Gompertz assumes that the "power to oppose destruction" loses equal proportions* in equal times; so that the intensity of mortality, supposed

* The word in the eighth page of the memoir cited is *portions*, which is a misprint or an oversight, as the formula immediately following shows. If x be the time, $a - bx$ loses equal portions in equal times, and $a \cdot b^{-x}$ equal proportions.

inversely proportional to this power, must be represented by the formula aq^x , where a is its value at the commencing age from which x years are reckoned, and q a constant depending on the rate of increase of the intensity. If, therefore, y be the number living at the end of x years, $y \cdot aq^x dx \times b$ is the decrement of that number in the time dx , where b is another constant; and this gives $dy = -abq^x y dx$, which integrated is of the form

$$y = lg(q^x)$$

where q , l , and g are to be determined. This can be done by three values of y out of the given table; and the result, hitherto purely hypothetical, can then be compared with the other parts of the table, by calculation of the values of the formula for different ages. The more convenient form of the above is

$$\log y = \log l \pm \text{no. wh. log. is } (\log \log g + x \log q)$$

where $\log \log g$ is taken without reference to the sign of $\log g$, and the upper or lower sign is used according as g is greater or less than unity.

Among other comparisons, Mr. Gompertz has made one with the Carlisle table from the age of 10 to that of 60, and another (deducing different values of l , g , and q) from 60 to 100. The two formulæ obtained are, using $\log^{-1}$ for the phrase "no. whose logarithm is," and x meaning the age of the parties,

$$\log y = 3.88631 - \log^{-1} \{ 2.75526 + .0126 x \}$$

$$\log y = 3.79657 - \log^{-1} \{ 3.74767 + .02706 x \}$$

In the first set of ages the discordance between the formula and the table is only in one instance as great as half a year; that is, there is only one instance in which the number deduced from the formula as alive at a given age represents the number living in the table at an age so distant from the given age as half a year. Several other comparisons, with other tables and different constants, give equally satisfactory results. Few who know the best tables of mortality will be inclined to think that their probable error is within half a year; so that, as we now stand, Mr. Gompertz's principle, namely, "that equal proportions of the 'power to oppose destruction' are lost in successive small equal times," is as well established for a large portion of life as any of the tables. It is remarkable that the approximate accuracy of the common method of finding an annuity on three joint lives, by substituting for two of the lives one life of the same value, is a consequence of the approximate truth of Gompertz's law. (See the 'Assurance Magazine,' July, 1859, vol. viii. p. 4.)

We now come to the practical exhibition of the law of mortality in tables. A very good account of the history of the subject, by Mr. Milne, appears in the 'Encyclopædia Britannica' article 'Mortality,' the references in which may be consulted by those who desire information on the state of the question in foreign countries. We shall in this article confine ourselves principally to English tables.

The obvious and simple mode of forming a table of mortality would be to take a large number of infants born alive, all of the same sex and in the same station of life. If the numbers left alive at the end of every year were noted, until all had become extinct, a column of ages, accompanied by an opposite column noting the number of survivors, would be a table of mortality in the most usual form. Such a table might be called a table of decrements. Let l_0 represent the number born, and l_x the number who survive to the age of x .

The formation of such a table might require a century of observation. To avoid this, the law of mortality must be assumed stationary; that is, it must be presumed that, out of those who reach, say age 70, the proportion who die in a year is now what it will be when an infant new-born reaches that age. This being assumed, let the members of a community be counted, and their ages registered; at the end of a year it will appear what proportion of each age has died. If the process be repeated in succeeding years, other sets of events are obtained, which may all be put together into one table, when the number has become large enough to secure the observed events representing the average, and to destroy the effects of accidental fluctuations. If then altogether k_x persons have attained the age x , of whom k_{x+1} have survived to the age $x+1$, it follows that the proportion who die in a year is $(k_x - k_{x+1}) : k_x$, which may be represented by m_x . A table of the values of m_x might be called a table of the yearly rates of mortality.

A table of yearly rates may be converted into a table of decrements, as follows. Assume a number l_0 to be born, then from the table of yearly rates,

$$l_1 = (1 - m_0) l_0, l_2 = (1 - m_1) l_1, \&c.$$

If the population, say of a town, remained unaffected, or sensibly unaffected by immigration or emigration, that is, if all who were born in the place, and no others, were registered in the burials of the place, the burial registers would form a mortality-table, provided the rate of increase of the population were steady and known. For, firstly, if the population had remained stationary for a long time preceding the commencement of registration, the yearly deaths and births being equal, and if the mortality had also remained stationary, the burials of any one year, the parties being distributed according to age, would show

the law of mortality as follows:—Suppose the registers of a year showed that M_0 died in their first year, M_1 in their second year, and so on, the equality of births and deaths shows that $M_0 + M_1 + M_2 + \dots$ must have been born in that year, and the stationary character of the law of mortality being assumed, it follows that of $M_0 + M_1 + \dots$ persons born, it is the law of the mortality that M_0 die in their first year, or that $M_1 + M_2 + \dots$ survive; similarly that $M_2 + M_3 + \dots$ survive two years, and so on. But if the population be in a state of increase, and if the annual ratio of increase be that of $1 : 1 + \mu$, those who die at the age $x - 1$ and x cannot be incorporated in the same table, since the first are a portion of a table beginning with a larger number of births. The former then must be reduced, or the latter increased, in the proportion of $1 : 1 + \mu$: so that if $M_0, M_1, \&c.$, be the deaths in the first, second, &c. years of age by the register, the table must run thus: of

$$M_0 + M_1(1 + \mu) + M_2(1 + \mu)^2 + \dots$$

persons born, M_0 die in their first year, $M_1(1 + \mu)$ in their second, and so on.

A table of mortality may also be given in the form of a table of the mean durations of life, calculated as in LIFE, MEAN DURATION OF. Or the table of mean durations may be calculated from the table of yearly rates, as follows:—Let e_n be the mean duration of the lives aged n , and m_n the yearly rate at the same age: then

$$e_n - \frac{1}{2} = (1 - m_n)(e_{n+1} + \frac{1}{2})$$

by which, beginning from the end of life, the mean duration at each age may be computed from that at the age next higher.

Various tables of these several kinds have been constructed, beginning with that made by Halley from the town of Breslau, and ending with that formed by the Equitable Insurance Office from its own materials, and with the Actuaries' Table presently mentioned. If we were to look to the wants of the subject, whether as a physical investigation or a statistical one, we should find that it is everywhere in the merest infancy. The fact of a difference of mortality between the two sexes is established, and it also seems to be known that where the occupations of females are not above their strength, their mortality is less than that of males; but no settled determination of the amount of difference has been obtained. As to whether married or single life is the longest, whether the age of the parents, or the relative age, affects the mortality of the children, whether the earlier children of a marriage differ in their law of mortality from the later, &c., we have no trustworthy information at all. In some foreign countries, as in Sweden and Belgium, the attention paid by the government to statistical subjects has produced some results which are worth a good deal; the reader may consult the article in the 'Encyclopædia Britannica,' already cited, for reference to them. We shall now give merely the dates and titles of the most remarkable earlier tables connected with the subject.

1538. Parish registers first kept in England.

1540–41. The statute 32 Henry VIII., c. 28, enabling ecclesiastical persons and corporations to grant leases for *three lives*, or *twenty-one years*. From this permission springs, we think, much of the attention which has been paid to the subject of life leases in England. It gave rise to certain tables of the value of leases which were called 'Æcroid's Tables,' and which were put together, as was thought by later writers, about the end of the reign of Henry VIII. They assume a rate of interest greater than 11 per cent. After the Restoration, when the interest of money had very much fallen, the ecclesiastical lessors began to raise their fines. This occasioned great dissatisfaction, and frequent representations to the House of Commons, which, though it passed no law, in several cases recommended to particular bishops, &c., an adherence to the old rule. Attention began to be turned towards the actual value of life. In 1662 John Graunt published his 'Natural and Political Observations on the Bills of Mortality,' often reprinted. In 1674, Sir William Petty, in a paper in the 'Philosophical Transactions,' proposed a law of mortality of the following kind: the probability of one life surviving another, after the age of 16, is inversely as the square roots of the ages. In 1685 were published the well known 'Tables for renewing and purchasing the leases of Cathedral Churches and Colleges,' the methods of which were certified to be correct by Newton, and which therefore have been frequently called Newton's Tables. About 1720, if not before, a letter called 'The Value of Church and College Leases considered,' was appended to these tables, and a very sharp controversy took place, which produced a great many pamphlets; the party of the lessees appealing to custom, the lessors showing from the value of life and interest of money that the church landlord dealt more leniently with his tenant than the layman, as was indeed the case. Among the writings which arose out of this controversy was 'The Gentleman's Steward instructed,' 1730, by John Richards, containing the most complete tables of annuities which had been published.

The work of Graunt and the political essays of Sir William Petty preceded, and probably stimulated the attempt of Halley to construct (in 1692) a table from the bills of mortality at Breslau, which was published in 1693. In 1699 came Dr. Davenant's 'Essay,' &c., containing extracts from some tables by Gregory King (afterwards pub-

lished entire), which Mr. Milne states to represent tables since made with great accuracy. Kerseboom's tables of lives (constructed from Dutch registers of annuitants) appeared in 1738, 1740, and 1742. De Moivre's 'Treatise on Annuities,' containing his celebrated hypothesis, was published in 1724; and Thomas Simpson's work on the same subject, containing a table deduced from London observations, in 1742. Deparcieux, in 1746, published his 'Treatise on Annuities,' containing his tables deduced from the lives of French annuitants, as well as from monks and nuns. These were the first tables in which male and female life were distinguished from each other.

The works of Price, Baily, Milne, &c., contain altogether a large number of tables, which we shall here no further notice than to give references to the works in which they may be found, with other matters connected with the same subject.

'Observations on Reversionary Payments,' by Richard Price, D.D., seventh edition, edited by William Morgan, London, Cadell and Davies, 1812.

'The Doctrine of Annuities and Assurances,' by Francis Baily, London, Richardson, 1816. This work, now out of print, has been translated into French, under the title 'Théorie des Annuités Viagères,' traduit de l'Anglais par Alfred de Courcy, Paris, Bachelier, 1836. There is also a spurious edition, issued ten or twelve years ago, which is an imitation of the type, &c., of the original.

'A Treatise on the Valuation of Annuities and Assurances,' by Joshua Milne, London, Longman & Co., 1815.

'On the Natural and Mathematical Laws concerning Population, Vitality, and Mortality,' by Francis Corbair, London, 1833. This work contains a large number of tables.

Reports (two in number) of Select Committees of the House of Commons on the Laws respecting Friendly Societies. Ordered to be printed, July 5, 1825, and June 29, 1827.

'Report of John Finlaison, actuary of the national debt, on the evidence and elementary facts on which the tables of life annuities are founded.' Ordered by the House of Commons to be printed, March 31, 1829.

'Library of Useful Knowledge,' treatise 'On Probability.' This anonymous work is by Sir John Lubbock and Mr. Drinkwater (Bethune), but by some mistake many copies were issued with Mr. De Morgan's name on the binding.

'Treatise on Friendly Societies,' by Charles Ansell, &c., London, Baldwin & Cradock, 1835.

'Tables showing the total number of persons insured in the Equitable Society from 1762 to 1829,' &c., by Arthur Morgan, London, 1834.

Mr. Rickman's various Reports on the Population Census contain tables deduced from them.

'Recherches sur la Reproduction et la Mortalité,' &c., par MM. Quetelet et Smits, Bruxelles, 1832; and 'Sur l'Homme, &c., ou Essai de Physique Sociale,' 2 vols., par A. Quetelet, Paris, Bachelier, 1835. These works exhibit for Belgium what we could wish to see imitated in England.

'Tables of Mortality, deduced from the experience of the Amicable Society during 33 years, ending 1841.' Published in 1841.

'Law of Mortality, deduced from the combined experience of 17 offices, embracing 83,905 policies, of which 40,616 are distinguished by denoting the sex of the lives assured, and by classing them into town, country, and Irish assurances.' Privately printed for the offices in 1843. This table was constructed on *policies*, not on *lives*: a person insured in two or more of the seventeen offices counted as two or more persons, all of whom were bound to die at the same moment. Perhaps this would make little difference in the general results, though it would be unsafe to assume as much. Again, though seventeen offices were combined, yet the Equitable and the Amicable put together make up far the largest part of the whole. The distinctions pointed out between male and female life (that is, *assured life*), are no doubt correct, and are very remarkable. Female life, though better than male life, appears worse among assured females than among assured males. But the *female* difference and the *Irish* difference are probably to be explained by reasons which more concern the offices than the student of the physical law of mortality.

The publications of the registrar-general commenced in 1839. It would be impossible to give any account of this valuable and ever growing mass of materials in any space which we could afford. And there would be little satisfaction to the reader of a few years hence in the perusal of what he would know must be then very imperfect. We hope that the registrar-general himself will soon feel it his duty to give the public a digest of results, with the proper references, and a complete list of his publications. And when, speaking with due official propriety, we mention the registrar-general, all who are conversant with the subject will know that we mean Dr. Farr, who is as much the guiding spirit of the Registry Office as Sir Rowland Hill is of the Post Office.

We shall now proceed to give some tables of mortality, namely, the Northampton and Carlisle tables, those of the Equitable Insurance Office, and Mr. Ansell's Friendly Societies' table. We shall give a brief description of each.

1. Northampton Table. This table was formed by Dr. Price from the burial registers at Northampton, between 1741 and 1780. He has not distinctly described the process by which he formed it. This table was for a long time the only one used by the insurance offices. It is

now known to give the probabilities of life too low at the younger and middle ages. Some of this (but probably not all) is due to the increased value of life in England since the middle of the last century. This table contains both males and females in nearly equal numbers. The accordance of the Northampton Table with De Moivre's Hypothesis at the middle ages of life is remarkably close. (Price, 'Obs. on Rev. Paym.,' vol. ii., p. 94.)

2. The Carlisle Table. The materials of this table were obtained by Mr. Milne from a tract published by Dr. Heysham of Carlisle, in 1797, containing the bills of mortality from 1779 to 1787, both inclusive. The proportion is ten females to nine males. From the verifications which this table has since received, it must be considered as the most correct representative of healthy life in England which exists. (Milne, 'On Annuities,' p. 404.)

3. The Equitable Table. The tract in which this is found is cited above. It represents the experience of the Equitable Society from 1760 to 1829, and agrees closely at the middle ages with the Carlisle

table. The agreement would be a little closer in most parts but for the following circumstance. In the formation of this table it is presumed that all those who discontinued their insurance lived, one with another, one-half of their year of discontinuance in the society. Now (throwing aside short insurances, which are always very small in number) the modes of discontinuance are only abandonment by neglect to renew the premium, and sale to the society. In the former case the parties live the whole year of discontinuance in the society, since their intention not to renew would be no bar to a claim on the part of their executors if their death took place during a year at the beginning of which premium had been paid; and it is well known that in the earlier history of every insurance office, abandonments were much more frequent than sales. And even in the case of sales to the office, it may reasonably be assumed, unless proof to the contrary were shown, that they take place, for the most part, shortly before a new premium becomes due, parties frequently choosing to take the benefit of the insurance as long as they can, and to sell when a new payment is

I. DECREMENTS OF HUMAN LIFE, ACCORDING TO THE NORTHAMPTON, CARLISLE, EQUITABLE, AND FRIENDLY SOCIETIES' TABLES.

approaching. It must therefore be supposed (unless, as before hinted at, specific proof from the records of the office be produced to the contrary) that the discontinuants, or a very large majority of them, lived the whole year of discontinuance in the office. This will make the mortality a little less than that represented in the table, though not much.

There is also a point on which, if our information be correct, the method of forming this table has been misapprehended. Those who study the subject are aware of the thing to which we refer ('Enc. Metr.,' article 'Mortality,' part ii., § 53, note), and will therefore comprehend the following. It is, we understand, the practice of the society in question to make up the registers on the first day of January, at which period every person insured during the previous year is put down as being of the *office age* which he had at his entrance. Now this office age means the age at the next birthday; that is, one with another, parties do not attain their office age till they have lived half

a year in the society. But on each first of January the parties insured during the previous year have, one with another, lived half a year in the society, so that they are correctly stated as being of their office age when the registers are made. The preface of this very valuable table is not sufficiently explicit on this and several other points.

4. The Friendly Societies' Table. The materials for this table were collected by the Society for the Diffusion of Useful Knowledge, and were discussed by Mr. Ansell in the work cited above, which should be in the hands of every one interested in the excellent institutions of which it treats. It embraces the history, as to mortality, of 24,323 years of life, among the labouring classes, from all parts of England indiscriminately, and from 1823 to 1828.

The explanation is as follows:—Of 10,000 infants born at Carlisle, 1539 would die in their first year, and 8461 would survive, while 4000 would live to 56 and upwards. In the Equitable Table, of 3922

II. YEARLY RATES OF MORTALITY UPON 10,000 LIVES ACCORDING TO THE NORTHAMPTON, CARLISLE, EQUITABLE, AND FRIENDLY SOCIETIES' TABLES.

persons attaining the age of 40, 43 and 44 die in the two succeeding years, leaving 3835 surviving at their 42nd birthday.

Of the three species of tables, this is the most useful for mathematical deduction, and the least adapted for a comparative view. The best way of using them for the examination of their relative bearings is to compare the *probable life*, as it is called, of the two, that is, the time in which the numbers living are reduced one-half. Thus taking the age of 31, we see that the numbers living in the Northampton table are halved at the age of 59, while in the Carlisle table this does not happen till the age of 67.

Thus of 10,000 persons attaining the age of 40, 130 die in the following year according to the Carlisle tables; while of 10,000 who attain the age of 41, 138 die in the next year. This species of table is the only one of the three which is immediately applicable to the comparison of two sets of data at and near a given age; while the one to which we now come serves to compare the total character of two sets of data from and after a given age. It also unites the fluctuations of different years, by compensation: thus looking at tables II. we should hardly suspect that closeness of resemblance between the Carlisle and Equitable tables, in the value of life, which is obvious in those marked III.

To avoid decimal points, 100 persons are supposed at each age: thus, 100 persons aged thirty enjoy among them 3086 years, according to the Friendly Societies' tables, or each of them, on the average, 30.86 years. This sort of table is much the best for a running comparison of two laws of mortality.

It must be observed that the two first of the preceding sets of tables attempt a degree of minuteness which cannot be supposed to be attainable with existing data. To distinguish between the decrements of two successive years, and the percentages of the two sets of deaths, would require much greater numbers of living at the two ages than ever have been found in the materials of a table. Nor is the regularity observable in these tables also observable in the observations which produced them; this result being obtained by hypothetical adjustments, so as to attain the nearest representation, in the main, of the

materials under investigation. This applies particularly to the old lives, which are but few in number, and present various diversities of fluctuation. Almost all the tables which have been constructed present some general results of utility; and we cannot but think that writers on this subject, by attending too much to minute comparison, and not enough to general indications, have not made all the legitimate deductions which the materials before them would have afforded. We proceed to some general account of the state of mortality, restricting ourselves to the last and present centuries, to life in England only, and to the general variations of mortality and the relative mortality of the sexes.

The circumstance which must strike every one as most remarkable, is the great increase which has taken place in longevity. To put this in a clearer light, we shall collect various tables of the mean duration of life, specifying the epochs of their collection. The tables formed from male lives only, have a capital letter; from female lives only, a small letter; from both, a capital and a small letter. At the bottom of each table is given the period in which all or most of the lives became extinct. The number in the table is the number of years enjoyed by ten individuals: thus in table T, at the age of 20, the mean duration of a single life is the tenth part of 293 years, or 29.3 years.

Comparing tables made from the same sex, or from the mixture of both, that is, looking at T, R, A, E, and G together for the males (P and F are made from the labouring classes exclusively), at t, r, and g for females, and at L l, H h, N n, and C c for both together, the general increase of longevity is sufficiently apparent. The older tables, made from burial-registers, will not prove more than the general fact, uncorrected as they are both for increase of population and migration. The great excess of the Carlisle Table, it must be remembered, is partly owing to the deaths from small-pox having been allowed for, which, though necessary in a table intended for subsequent use among a vaccinated population, prevents the comparison between the Carlisle and preceding tables from being altogether fair. The tables A and F are very similar, and show that the life of the more provident class of labourers (who resort to Friendly Societies) is now as good as those of the Amicable Insurance Office in the last century. That Society is supposed not to have been, in former times, so careful in the selection of lives as the modern institutions of the same kind. This was probably the case, though another circumstance may have operated still more on the table. Up to the year 1808, or thereabouts, no lives older than 45 were taken; so that, while the registers of the Equitable

Society have been constantly recruited with selected lives from 45 to 60, as well as at the lower ages, those of the Amicable Society have not had the same advantage above the age of 45. We think however that much of the difference between the two arises from the earlier period which the tables of the latter Society represent.

That the life of a Chelsea pensioner, who is presumed to be a worn-out soldier, should be better than that of the most provident class of labourers, may seem startling at first; but it must be observed that this is only after the age of 40; and the explanation of this circumstance hangs upon another which it is essential to notice.

Let us compare the *relative* lives of the young and old in the different tables; that is, for instance, dividing the life of a person aged 20 into 1000 parts, we ask how many such parts there are found in the life of 60. Ranging the results in order of magnitude,

* Mr. Lubbock's corrected table ('Library of Useful Knowledge,' PROBABILITY) would have been preferable, but the mean duration is not computed.

† Formed some years ago, from the experience of the Society, which has existed since 1706. Their records however can only be said to begin from 1740.

we find that, the life of 20 being 1000 in every table, the life of 60 is as follows:—

P: 503	t: 388	R, 355
Ll, 429	Hh, 385	F: 354
T: 396	G: 375	Cc 345
N n, 395	r, 372	A: 342
g: 313	O o, 360	E; 333

To show that this distribution does not arise from the method of forming the tables, we have put the comma after all symbols of tables formed from burial-registers (except the Carlisle, which has been in every point too carefully corrected to allow it to rank in method of formation with the rest) and subject to errors of population, and the colon after those tables which have been formed in such a manner that no errors of the preceding kind can appear. It will then readily be seen, as a general result, that old life is relatively longest in those tables in which life in general is absolutely shortest, and that tables formed from female life exclusively hold a mean rank. We have observed the same thing in many other tables, and we think a general explanation can be given. It is well known that the admirers of nature (many of them, at least) formerly included savage life in their panegyrics, and contrasted the uniform good shape and activity of many wild tribes with the frequent deformity and debility of the civilised man: this opinion however has declined since it was remarked that such uniformity of strength was probably a consequence of its being impossible for a disabled or weakened individual to subsist where the highest strength and activity are required to procure common necessities. Something of the same sort seems to take place with regard to mortality: where the predisposing causes of death are strong and inadequately met, the weaker constitutions swell the tables of mortality at the younger ages, leaving a relatively stronger class to face the chances of more advanced life. Thus in the case of a disabled soldier, he who can last to 60 is half as good, in point of duration, as he was at 20; while the insurer in the Equitable is only one-third as good relatively, and absolutely not nearly so good as the former.

It is sufficiently obvious that female life is better than male, from every comparison of the preceding tables, and almost at every age. To compare these durations, let us suppose ten individuals at every age in T and t, R and r, G and g. If we then take the united amounts of their average lives from 15 to 85, we find that, one age with another, and for equal numbers of males and females similarly distributed,

For 1000 years of	{ King William's Tontine 1104	} Years of female	
male life there	{ Chester Tables . 1112		life.
are in the	{ Government Tables 1163		

There appears then to have been a slight increase in the comparative goodness of female life: from which those who admit it must conclude that improved medical science and greater accessibility of comforts lengthen the life of females more than that of males. At any rate the other extreme is tolerably well proved by foreign tables, Belgian and Swedish (we have none in this country to settle the point), namely, that when the lives of women are employed in laborious occupations in the open air, they are materially shortened in duration. In Belgium the lives of women living in the country are, on the whole population in the country (mostly labourers, of course), shorter than those of men; while in the towns they are longer, the proportion above-mentioned being that of 1000 to 1071.

On the mortality of the infant periods of life there is but little information. All tables, except the Government Annuity, unite in showing that the value of life improves up to a period which differs in different tables; being six years of age in the Northampton Table, and five in the Carlisle. With respect to the Government Table it must be observed, that the numbers in the first years of life are small, and also that all the lives are selected. If then it be more easy to select the best lives from among infants than from among grown people, the anomaly of these tables is explained; and the explanation is not difficult to admit, if we remember that the selection is made in most cases by the relations of the party selected, who are perfectly aware both of the state of health of the infant (generally more marked than that of a grown person) and the longevity of its ancestors.

We are of opinion that the Carlisle Table is more likely to represent truly the very old periods of life, not from any greater quantity of materials, but from a better theory having been applied in their formation. It has been very common to end tables with the oldest lives observed in them: thus the Equitable Table ends at 97, because the latest of the deaths from which it was formed (5144 in number) took place at that age. This is not correct in principle, and is the same thing as if, a pair of dice having been thrown a large number of times (say 10,000), it should be inferred that no runs of doublets should ever be calculated on of longer duration than those observed during the course of the throws. In the case of the dice we can calculate beforehand what was the chance of longer runs; and in the table of mortality we have no *a priori* calculation, but only observation of instances: this throws a difficulty in the way, but that difficulty is not properly met by exclusion of all that has not happened as impossible. For the calculations connected with annuities, &c. it is of little consequence, because cases rarely occur in which the purchasing parties are above 80;

at which age the chance of living twenty years is so small, that it would not much affect the pecuniary results if those who could get over the period between 80 and 100 years were afterwards supposed to live for ever. But for the determination of the physical laws of the duration of life, such termination of the tables at the oldest age of observed death is wholly inadmissible.

Mr. Babbage has published ('Comparative View of Institutions for the Assurance of Lives,' London, 1826; Table XII., Appendix, from 'Easton's 'Human Longevity,' Salisbury, 1799) a table formed from 1751 persons who attained the age of 100, which we subjoin, with such additions as will make it correspond with those given before:—

Age.	No. living.	Decrement.	Yearly Rate on 1000.	Mean duration. 100 Persons.	Age.	Age.	No. living.	Decrement.	Yearly Rate on 1000.	Mean Duration. 100 Persons.	Age.
100	1751	164	94	809	100	126	71	8	113	767	126
						127	63	7	111	758	127

114	294	31	106	826	114						
115	263	29	110	817	115	141	10	1	100	500	141
						142	9	1	111	450	142
116	234	25	107	813	116	143	8	1	125	400	143
117	209	24	115	804	117	144	7	1	143	350	144
118	185	22	112	801	118	145	6	1	166	300	145
119	163	20	123	803	119						
120	143	17	119	808	120	146	5	1	200	250	146
						147	4	1	250	200	147
121	126	14	111	811	121	148	3	1	333	150	148
122	112	13	116	805	122	149	2	1	500	100	149
123	99	11	111	804	123	150	1	1	1000	50	150
124	88	9	102	799	124						
125	79	8	101	784	125						

This table is the necessary consequence of that very large amount of dubious testimony which exists, in various places, upon instances of particular longevity. Looked at separately, there are no means of refuting any one instance; but their united effect is beyond all credibility. The ages of many of these persons must have been ascertained by their own statements of the earliest public events within their memory, and it is not unlikely that very old persons frequently confuse what they have heard talked about in their infancy with what they have seen themselves. There is also a natural tendency to exaggerate great age. Enough however remains, when every possible allowance has been made for error, to show that the remaining life of a person aged 100 years is not so very small as it is generally believed to be; and we strongly suspect that the last 25 years of the Carlisle Table are no exaggeration, but really considerably short of the actual law which prevails among the middle classes of society.

MORTAR. The cementing or binding materials used in building operations, which have a lime base, in one or other of its forms, are known technically by the name of MORTARS; and they are either composed of the ordinary varieties of limes and sand; or of plaster, or of cement, mixed with the same material; or again, in certain cases, of limes mixed with peculiar volcanic productions, such as PUZZUOLANOS and TRASS. The term mortar is therefore a generic one, though its use is almost confined in practice to the mixtures of lime and sand employed for the purpose of building.

In the article LIME, reference has been made to the theoretical conditions affecting the proportions of sand it may be advisable to mix with the respective varieties of that material; but it may be here stated that precisely in the ratio of the expansion of the lime during its absorption of water is it able to support a larger volume of sand for the purpose of mortar making. It thence follows that, as the hydraulic limes, or those which set under water, do not expand much under those circumstances, they support a smaller quantity of sand than the rich, or pure, limes can do. In fact, the best hydraulic limes will not carry, to use a workman's phrase, more than about $1\frac{1}{2}$ to 2 proportions of sand to 1 of the lime; both being measured in bulk, and after the slaking of the lime; whilst the rich limes will carry as much as 3 proportions of sand to 1 of lime, when made into mortar. Thus the better a lime is fitted for the purposes of external masonry, the smaller will be the proportion of sand it will bear; and to illustrate this principle by the practice of our London, or southern, builders,

it may suffice to state, that the chalk lime is usually mixed with 3 portions of sand to 1 of lime; the semi-hydraulic graystone lime, from the chalk-marl, with $2\frac{1}{2}$ sand to 1 lime; whilst the blue-lias lime is mixed with proportions of $1\frac{1}{2}$ sand to 1 lime.

The operation of ordinary mortar making depends for its success upon the energy and the stability of the crystallisation of the lime; for the sand simply acts the part of furnishing a nucleus around which the crystals may arrange themselves, and unless it should happen to contain a notable proportion of silica in the soluble state it will remain chemically inert. Now the pure carbonates of lime yield a caustic lime, which is very easily soluble in water, and which does not crystallise at all when kept in large masses; and the only lime compounds able to solidify under water—whether salt or fresh—are those which contain the various proportions of silicate of alumina, described in the article LIME. It is on this account that in countries, such as Holland, or Central Italy, where the natural limestones are remarkably pure carbonates, it is customary to introduce into the mortars to be employed in hydraulic building the trass and puzzuolano obtained in the same districts, because those materials are composed of the dehydrised silicate of alumina, which when ground fine will combine chemically with the pure hydrated carbonate of lime. It was supposed that any dehydrised silicate of alumina would produce this result, and the French and German engineers, following the occasional practice of the ancient Romans, actually substituted underburnt-brick dust for the trass or puzzuolano, in some marine walling, and some canal works. But it would appear that peculiar conditions of the silicate of alumina are requisite, at least in the case of mortars intended to resist the action of sea-water; because in almost every instance the mortars composed of expounded bricks, lime, and sand, have disintegrated after a short exposure to the sea; those which were only exposed to the action of fresh water have resisted more successfully, and it is notorious that the Roman mortars possess a very extraordinary hardness and durability, even at the present day. Without dwelling upon these still rather obscure points in the theory of the action of limes, it may suffice here to observe that the above considerations point out the nature of the mortars required for particular positions, or for particular works. Thus, the mortars required for hydraulic works in sea-water must be composed of the most energetic cements, and the latter must even be used without any mixture of sand, if the mortars are intended to be at once exposed to the action of the sea; if, however, the mortars can be protected for a sufficient length of time to allow the crystallisation to take place effectually, the cements may be mixed with sand, or even the best hydraulic limes may be used. For river work, in non-tidal rivers especially, the best hydraulic limes should be used; and for all exposed walling, the common descriptions of hydraulic lime may be resorted to; whilst the purer limes should be reserved for internal works, and for surface renderings of small thickness.

In the preparation of the various mortars the first operation to be performed is the slaking of the lime or cement. In the case of the latter class of materials, which are always ground before being used, the only precaution to be observed is to avoid bringing them into a fluid state; or, in other words, it is advisable only to add enough water to bring them to the consistency of a tenacious modelling clay; especial care being also taken to moisten the stones or bricks to be used simultaneously with them, so as to prevent any absorption of moisture from the cements. In the case of the hydraulic limes, when used without being previously ground, the slaking is performed either in pits or by aspersion, or by immersion; and the object to be obtained is to cause the lime to fall into a fine dry powder, in the state of the hydrate; which powder, however, would not possess the power of crystallising without the addition of a further quantity of water. This additional quantity of water is added at the same time as the sand, introduced for the purpose of affording nuclei around which the crystals of the lime may arrange themselves; and it is indispensable that the whole of the lime in a mortar should have been thoroughly slaked before it is placed in the work. At the present day, in all large building operations the mortar is made by means of PUG-MILLS, or mortar-mills, the latter being formed of large stone or iron wheels revolving in hollow basins; and when those machines are properly used the mortar is more uniform in quality, and more free from *core* than in the ordinary process of manufacture. The *core* is, in fact, the under-burnt lime, which slakes, when in lump, less quickly than the rest of the lime, and is therefore exposed to take on its action of expansion at a different period; this action would, perhaps, disturb the crystallisation of the rest of the work, and great precautions are required to prevent its occurrence; it is known amongst workmen by the phrase of "the lime blowing." The pure rich limes are more exposed to this class of action than even the hydraulic ones; because in the process of calcination some portions of the limestone become not only *under*, but also others become *over* burnt, and the periods of slaking of the *core*, produced by either of those causes, differ materially from that of the normal lime. Great care is therefore required in slaking the rich limes, and the old Romans seem to have adopted the custom of slaking them at least three years before the mortars were made; a far greater quantity of water may be used with these limes than with the hydraulic varieties, and indeed the London builders, when about to employ the ordinary chalk lime for plastering purposes, actually *run* it, as they say; or they reduce

it to a fluid state and run off the liquid into a tank, where the excess of water is allowed to evaporate. This operation of running would effectually destroy any of the hydraulic limes, and it is important with the latter only to present the quantity of water strictly required for its hydration. Unfortunately working men are so careless that it is practically impossible to ensure the observance of the precaution of keeping the bricks or stones so wet as that they should not be able to abstract moisture from the mortar; and it thus almost always happens that, even in the manipulation of hydraulic limes, a larger quantity of water is used than would theoretically be required.

The mixture of the sand with the lime, or cement, is either effected by hand or by means of the pug-mill; and the proportion above indicated for the various descriptions of lime should be strictly adhered to, and ascertained by actual measurement; the lime itself being slaked, reduced to powder, and measured in that state. In ordinary operations it may not be necessary to observe such extreme accuracy, but for hydraulic works it is essential that all precautions should be taken; and therefore it is equally essential that the proportions of the lime and of the sand should be ascertained by some safer test than the eye of the labourer charged with making the mortar. Be this as it may, the sand to be used for mortar should be a clean, sharp, angular, silicious sand; free from loam, clay, and large lumps of stone, or of oxide of iron: and it must be distributed as equally as possible through the mass.

The mortars obtained by the use of trass and puzzuolano do not contain the same quantities of sand which they would ordinarily do, because the trass, &c., replace it to a very great extent. In the north of Europe it is customary to mix 3 parts of lime in powder, 3 parts of trass, and 3 of sand for hydraulic works; and in the south of Europe, 33 parts of lime with 45 of puzzuolano, and 22 of sand; but the value of these mixtures depends, after all, on the care and attention with which the various ingredients are brought in contact with one another. Occasionally other substances, such as smith's ashes, pounded tiles, the roasted clay nodules of the ironstones, &c., have been mixed with lime and sand in the preparation of mortars; and they communicate to them some unimportant qualities of colour, or even at times some additional powers of setting, which render their use in particular places desirable, as for instance, for pointing old brickwork, or for bedding chimney-pots, or other analogous details of a building which are much exposed to variations of atmospheric conditions. The ordinary pointing mortar is made from the purer rich limes carefully slaked and prepared for the purpose.

In the neighbourhood of Paris the gypsum, or sulphate of lime, is frequently used as a mortar, for walling purposes in positions which are not exposed to much humidity; and this description of mortar is often used as a temporary protection to the slower setting hydraulic lime mortars in sea-water.

MORTAR-BOATS. Under the word GUN-BOATS the present mode of arming small vessels has perhaps been sufficiently noticed. The increased use of shells in naval warfare, to be fired from ordinary cannon, converts, in fact, every ship-of-war into a bomb-vessel; hence the term mortar-boat will not long designate any particular build of vessels, although a few small craft of light draft of water are still so called in the navy, but the term will merge into that of gun-boat.

MORTARS are pieces of ordnance which, compared with guns, are very short, and which are employed to throw shells or carcasses at considerable elevations (generally at 45° , but sometimes as much as 70°), in order that the missile may range to a great distance, and, by falling nearly vertically upon the object (a barrack, magazine, or casemate), may crush it by the momentum acquired in descending. Mortars are either of iron or brass; they rest upon solid beds, and the trunnions or cylinders upon which they turn, in giving the required elevation, are placed at the lower extremity of the piece. A mortar platform, in a battery, should be very strong, in order that it may bear the great recoil or shock of the piece when fired; and it should be carefully laid in a horizontal position.

The calibres of mortars in the British service are $4\frac{1}{2}$, $5\frac{1}{2}$, 8, 10, and 13 inches. All these different kinds of mortars are used on land, and the two last are also employed in the navy; but in this latter service the pieces are about 16 inches longer than the land-service pieces of the same calibre, and are much heavier, the sea-service 13 in. weighs 101 cwt. and the land-service 36 cwt. The two first-mentioned are sometimes called royal mortars.

By varying the charge of powder in the same mortar, it has been found that there is a particular elevation which, with each charge, gives a longer range than is obtained from an equal charge at any other elevation. It has also been found that the elevations which give the longest ranges differ much in two mortars of different calibres, but of like proportions, even when charged with quantities of powder bearing the same proportion to the weights of the shells, but for the sake of simplicity they are all generally fired at 45° , and the tables are all arranged for that elevation.

It has been supposed that mortars were employed in the year 1495, at the siege of the castle of Naples, but on no other ground than a statement that artillery of considerable magnitude was conveyed into Italy with the army of Charles VIII. In 1588, however, the use of mortars must have been well known, since, in the Appendix to the 'Colloquies of Tartaglia,' which was published in that year, the method

of filling and projecting carcasses is fully described: and it appears that in the same year shells were thrown from ordnance at the siege of Wachtendonk. [BOMB.] Red-hot shot were thrown from mortars at the siege of Bremen, by the Swedes, in 1665.

The first artillerists were somewhat capricious in the formation of their great ordnance; and among the various kinds which they devised may be mentioned what were called Partridge mortars. These had one great central bore for the reception of the shell; and about it, on the face of the muzzle, were sunk thirteen chambers, each of which contained a grenade. The shell and grenades were discharged at the same time, and in the air they must have appeared like a flight of birds; from which circumstance, no doubt, the name of mortar was taken.

The Dutch engineer Coehorn invented a small mortar for throwing grenades into the covered-ways of places. They were capable of being carried about and served by one man; consequently they could be readily brought up to a convenient spot, and rapidly fired when it was intended to drive the defenders from behind the parapets. In the French service *Pierriers* (small mortars loaded with stones) are still employed for the same purpose.

In the year 1771 an experiment was tried at Gibraltar on the discharge of stones from an excavation in the rock. The figure of the excavation is a parabolic conoid, whose axis is 4 feet long, and whose diameter at the muzzle is 3 feet. It was charged with 27 lbs. of powder and 1470 stones; and, on the explosion taking place, nearly one-fourth of the stones were projected to the distance of 100 yards. There are several rock-mortars, as they are called, at Malta, and such may on many occasions be very useful both in the defence and in the attack of a fortified place.

MORTGAGE. A general notion of a mortgage may be collected from the following passage in Littleton (§ 332), who treats of mortgages as then in use, under the general head of estates upon condition.

"If a feoffment be made upon such condition, that if the feoffor pay to the feoffee, at a certain day, 40*l.* of money, that then the feoffor may re-enter, &c.,—in this case the feoffee is called tenant in mortgage, which is as much to say, in French, as *mortgage*; and in Latin, *mortuum vadium*. And it seemeth that the cause why it is called mortgage is, for that it is doubtful whether the feoffor will pay, at the day limited, such sum or not: and if he doth not pay, then the land, which is put in pledge upon condition for the payment of the money, is taken from him for ever, and so dead to him, upon condition, &c. And if he doth pay the money, then the pledge is dead as to the tenant, &c."

The money thus agreed to be paid by the feoffor must be supposed to be money borrowed from the feoffee, or the amount of a debt due from the feoffor to the feoffee, though Littleton does not expressly say so. According to the terms of this contract, if the feoffor or the feoffor's heir did not pay the money at the time appointed, the land became the absolute property of the feoffee.

The *mortuum vadium* of Glanville (book x.) is evidently a different thing from the *mortuum vadium* of Littleton, and Glanville's explanation of the term seems more applicable to his *mortuum vadium*, than Littleton's is to the mortgage which he describes. "When an immovable thing," says Glanville, "is put into pledge, and seisin of it has been delivered to the creditor for a definite term, it has either been agreed between the creditor and debtor that the proceeds and rents shall in the meantime reduce the debt, or that they shall in no measure be so applied. The former agreement is just and binding; the other unjust and dishonest, and is that called a mortgage, but this is not prohibited by the king's court, although it considers such a pledge as a species of usury." (Beames' *Transl.*)

Littleton describes the old and strict law of mortgage; but the courts of equity gradually introduced such modifications as to convert a mortgage from its ancient simplicity into a very artificial and complicated arrangement. A mortgage is a contract, and therefore requires two persons at least, one of whom borrows and the other lends money. The borrower is the owner of land which he conveys or transfers as a security to the lender of the money: the borrower is called the mortgagor, and the lender is called the mortgagee. The whole transaction is properly termed a mortgage; but the name is sometimes applied simply to the debt. The nature of this contract, as it is now understood, will best appear from a brief enumeration of the essential terms of the instrument called a mortgage deed. For the sake of simplicity, the case of a mortgage in fee may be taken as the example; and the remarks which follow must be considered as applicable to that description of mortgage.

The instrument of mortgage is a deed indented. It commences by reciting that the mortgagor is the owner in fee simple of the lands which it is intended by the deed to convey to the mortgagee, and that the mortgagee has agreed to lend him a certain sum of money on the security of the lands. It is then declared that, in pursuance of the said agreement, the mortgagee has paid to the mortgagor the sum of money which he (the mortgagee) has agreed to lend. The mortgagor then conveys to the mortgagee and his heirs the lands in question, with a condition that if the mortgagor, his heirs, executors, administrators, or assigns, shall pay to the mortgagee, his executors, &c., the sum of money borrowed, with interest for the same at the rate in the instru-

ment mentioned, upon a future day, which is named in the deed (generally a year from the date of the mortgage deed), without any deduction or abatement whatsoever, the deed shall then cease and be void to all intents and purposes, or that the mortgagee shall reconvey the premises to the mortgagor. In addition to this conveyance of the lands, the mortgagor promises and undertakes to pay the principal money borrowed, and interest on the same, at the rate and at the time before mentioned in the instrument; and he also covenants (as the legal phrase is) that he has full right to convey the lands in the manner expressed in the previous part of the instrument. It is further agreed that, after the mortgagor shall have failed to pay the principal sum of money, and interest, or any part thereof, as before agreed, the mortgagee, his heirs, or assigns, may take possession of the lands so conveyed as aforesaid, and use and enjoy them, and take the rents and profits, without any hindrance or interruption from the mortgagor his heirs, executors, administrators, or assigns, or any other person or persons. It is also provided that until the mortgagor shall have made such default in payment as aforesaid, he, his heirs, or assigns, shall hold and enjoy and receive the rents and profits of the lands without any interruption or hindrance from the mortgagee, his heirs, or assigns. In many mortgage deeds it is also provided, that if the principal money and interest, or any part thereof, are not paid at the time agreed on, the mortgagee may sell the mortgaged lands (giving proper notice to the mortgagor of such his intention, if notice is provided for by the instrument): it is also provided that after paying out of the proceeds of the sale, and out of any rents or profits which he may have received from the lands, the costs and expenses of the sale, and all other expenses incurred in the execution of the trust for sale, and retaining what is due to him for principal and interest, the mortgagee must pay the surplus, if any, to the mortgagor, his heirs, executors, administrators, or assigns, or as he or they shall direct. In deeds which contain a power of sale, it is usual to insert a proviso, that such power of sale is not to destroy or prejudice the mortgagee's right of foreclosure.

These are the essential parts of a mortgage-deed, which is varied according to the estate or interest in the lands which the mortgagor conveys to the mortgagee, and according to the special agreement of the parties. By the execution of the deed, the estate of the mortgagor in the lands mortgaged is conditionally transferred to the mortgagee, but the mortgagor's estate is not forfeited till he makes default in payment of the money borrowed and interest at the time named in the deed. The money borrowed is however seldom paid at the time agreed on, the consequence of which is that the mortgagor's estate is forfeited by his not fulfilling the condition, and the mortgagee becomes the absolute legal owner of the land, or of such estate in it as was conveyed to him. He can then bring an action of ejectment against the mortgagor, if the mortgagor is in possession of the land, without giving him notice; and he can do this even before default in payment, unless it is agreed by the mortgage-deed that the mortgagor shall remain in possession till he makes default, and a clause to this effect is commonly inserted in the deed. After the mortgage is made, the mortgagor cannot make a lease of the lands without the mortgagee's consent, for he has no interest in the land out of which he can create a legal estate; and if any such lessee gets possession of the land, the mortgagee may eject him. But the lessee who claims by a title prior to the mortgage is not affected by the mortgage transaction, though, after default is made and he has notice from the mortgagee, he is bound to pay to him the future rents and those which are then due.

There has been considerable discussion as to the nature of the relation of the mortgagor in possession and the mortgagee; and this relation has been supposed to be that of tenant and landlord, the nature of the tenancy varying according as we contemplate it before or after default. But this seems an erroneous view of the legal effect of the contract, and the supposition of a tenancy is perfectly useless for the explanation of the rights either of the mortgagor or mortgagee, which are determined by the instrument of mortgage, and by the well-established jurisdiction of courts of equity in matters of mortgage.

From the time of default being made, the several interests of the mortgagor and the mortgagee in the land must be considered as chiefly belonging to the jurisdiction of equity. When the mortgagee, by default of the mortgagor, has become the absolute legal owner of the lands, the mortgagor possesses what is called the equity of redemption. This equity of redemption is considered by courts of equity as an estate in the land: it may be devised by the mortgagor, and, in case of his intestacy, it will descend to his heir; it may be sold, or it may be mortgaged; it is subject both to dower (in equity, by 3 & 4 Wm. IV., c. 105) and curtesy; and it may be settled like a legal estate.

By the statute 1 Vict., c. 28, made for the purpose of explaining the statute of limitations (3 & 4 Wm. IV., c. 27), it was enacted, That any person entitled to or claiming under any mortgage of land (as defined by the last-mentioned act) may make an entry or bring an action at law or suit in equity, to recover such land, at any time within twenty years next after the last payment of any part of the principal money or interest secured by such mortgage, although more than twenty years may have elapsed since the time at which the right to make such entry or bring such action or suit in equity shall have first accrued. This act was passed to protect the mortgagee who allows the mortgagor to continue in possession of the land or in the receipt of

the rents and profits; and it secures to him his rights for twenty years after the last payment of principal or interest by the mortgagor. By the 3 & 4 Wm. IV., c. 27, when a mortgagee has got possession of the land or receipt of the profits, the mortgagor, or the person claiming through him, can only bring a suit to redeem the lands within twenty years next after the commencement of such possession or receipt, or within twenty years from the time when the mortgagee or the person claiming through him last acknowledged in writing to the mortgagor, or some person claiming his estate, or to the agent of such mortgagor or person, his title of mortgagor or right to redemption. The mortgagor, or the person claiming under him, may therefore, at any time within the limits above-named, tender to the mortgagee his principal money and interest, and claim a reconveyance of the lands; and if the mortgagee will not accept the tender and reconvey, the mortgagor may compel him by filing a bill in equity for the redemption of his lands.

A mortgagee can transfer his mortgage to another. The transfer or assignment as it is generally called, consists of two parts expressed in one deed, the transfer of the debt, and the conveyance of the land, which is the security for the debt. If the mortgagor is not a party to the assignment, the assignee takes the mortgage exactly on the terms on which the assignor held it at the time of the assignment. If therefore the mortgagor should happen to have paid the whole or any part of the debt, the assignee, in coming to a settlement with him, must submit to allow such payment in diminution of the original debt which the assignor affected to assign to him.

Though the mortgagee, after the mortgagor's default in payment of the principal money and interest, has the absolute legal estate, he is still considered by courts of equity only to hold it as a security for his debt. The legal estate in the land will descend to the mortgagee's heir, or will pass by his will, if duly executed; but the heir or devisee takes only the legal estate in the land, and the money or debt (as a general rule) belongs to the mortgagee's administrator or executor.

If the principal money and interest are not paid at the time agreed on, the mortgagee may file a bill of foreclosure against the mortgagor. By such bill the mortgagee calls on the mortgagor to redeem his estate forthwith, by payment of the principal money, interest, and costs; and if the mortgagor does not do this within the time named by the decree of the court (which is generally within six months after report has been made of what is due for principal, interest, and costs), he is for ever foreclosed and barred of his equity of redemption, and the mortgagee becomes the owner of the land in equity, as he was before at law. If the money is paid at the time named, the mortgagee must reconvey the land, and deliver up to the mortgagor all the deeds and writings in his possession relating to the land.

If both the mortgagor and mortgagee are living at the time when the lands are redeemed, and nothing has been done by either party to assign or transfer his interest to any other person, the transaction is a very simple one: the mortgagor pays his debt and interest, and the mortgagee reconveys the lands. The settlement of accounts between the mortgagor and mortgagee may be rendered more difficult by the circumstance of the mortgagee having received the rents, for which the decree for redemption provides that he must account. It may however happen that the mortgagor or mortgagee is dead, or that they have severally disposed of their interests in the lands, or all these events may have happened, which renders the settlement much more complicated.

To take the case of mortgagor and mortgagee being dead. As every mortgage transaction implies a debt from the mortgagor to the mortgagee, which he is bound to pay, even if there are no covenants for payment in the mortgage-deed, it followed that, according to the general rule of law, his personal estate was in the first instance liable to pay the mortgage debt, unless he had by his will made a different provision for payment of it. Thus the heir or devisee of the equity of redemption might be entitled to call on the administrator or executor to pay the mortgage debt. If however the lands in question were not mortgaged by the intestate or devisor, but the equity of redemption descended or was devised to him from or by the mortgagor, or if he purchased the equity of redemption, his personal estate was not liable to pay the mortgage debt; but the person who derived his title to the land from such intestate, devisor, or purchaser, took it subject to the burden of the mortgage debt, and this is still the law as to lands devolving under wills dated previously to the 1st of January, 1855. For other cases the law is now altered by 17 & 18 Vict., c. 113, so that land in mortgage passes to the heir or devisee *cum onere*.

When a mortgage deed contains a power of sale, which is exercised in the lifetime of the mortgagor, the surplus money is personal estate; but if the sale is effected after the mortgagor's death, the money belongs to his heir or the devisee of the lands.

The person entitled to receive the debt is the administrator or executor of the mortgagee; for, as already observed, the land is only considered as a security for the debt, which the mortgagor has bound himself, his heirs, executors, and administrators, to pay to the mortgagee, his executors, administrators, and assigns. Thus, whether the mortgagee dies without having or after having assigned his mortgage, the money is a debt due to the personal representative of the mortgagee, or to his assignee, or to the personal representative of the assignee, if the assignee is dead. When the debt is received by the person entitled to receive it, the person who has the legal ownership of the land, whether he be heir or devisee, is bound to convey it

to the person who, on the payment of the debt, becomes entitled to the legal estate. In such case, on payment of the debt to the person entitled to receive it, the heir or devisee is by a fiction converted into a trustee for the person entitled to the land. The mortgagee may, however, by express declaration, convert the mortgage debt into land (according to the technical expression), and make it pass as land by his will, in which case the devisee will have the same title to the money as he would have had to the land if it had been absolutely the property of the mortgagee.

When the mortgagor has mortgaged his equity of redemption (which he may do as often as he pleases), every new mortgagee has his claim on the land as a security for his debt, according to the order in which his mortgage stands. This is the general rule; but it is subject to various exceptions, which depend on particular circumstances. Thus a mortgagee of the equity of redemption will be postponed, as to his security, to a subsequent mortgagee who has advanced his money without notice of the prior mortgage, if such subsequent mortgagee should be able to obtain the legal estate.

If a second mortgagee obtains the title-deeds of the estate, this will not give him a preference over a prior legal mortgagee, unless the prior mortgagee has parted with or failed to get possession of the title-deeds for fraudulent purposes, or through gross negligence. But though the second mortgagee has no priority, when there is neither fraud nor negligence, he will not be compelled to give up the title-deeds to the first mortgagee, unless the first mortgagee pays him his debt and interest.

A legal mortgage is effected by an instrument which transfers the legal estate. When a mortgagor makes a second mortgage, and uses the form of a legal conveyance, this also is called a legal mortgage, though there is no transfer of any legal estate, for the legal estate is already conveyed to another person. This kind of mortgage may be called a mortgage of an equity of redemption, by way of distinguishing it from the equitable mortgage next mentioned. An agreement in writing to transfer an estate as a security for the repayment of a sum of money, is called an equitable mortgage, because it gives the intended mortgagee a right to have a legal mortgage, and in a court of equity gives him in fact all the rights of a legal mortgagee. A deposit of the title-deeds of an estate, or of the copy of court-roll, as a security for a debt contracted at the time of the deposit, or previously to the deposit, constitutes an equitable mortgage. An equitable mortgagee, by deposit of title-deeds, has a preference over a subsequent purchaser or mortgagee who obtains the legal estate with notice of the equitable mortgage.

If the mortgagor is not seised in fee, but has only a limited interest in land, as a lease for years, the mortgagor by taking an assignment of the lease, becomes liable for the rent, and to the covenants contained in the lease, though he has never taken possession of the premises included in it. The same rule was for a time held to apply to an equitable mortgagee by deposit of title-deeds [LEASE]; but in a recent case it was decided that the equitable mortgagee is not liable to such covenants (*Moore v. Choat*, 8 Sim. 508), and so the matter stands at present. See also *Moore v. Greg*, 2 Phill., 724.

The preceding remarks apply to mortgages of land only, in which there are many peculiarities which arise from the condition of legal ownership of land in this country. But other kinds of property may be mortgaged, such as chattels personal, a life-interest in a sum of money, or a policy of insurance, or a ship, or shares in a ship. The subject of pawning or pledging of goods is treated under PLEDGE, and also the rules of the Roman law as to *Hypotheca* and *Pignus*. The equitable lien on land, which is classed among mortgages by some writers, is briefly noticed under LIEN; and mortgages of ships under SHIP.

No attempt has been made to lay down all or the greater part of the rules applicable to mortgages. The explanation of these rules would fill a large volume. The general principles of all mortgages are however here laid down, and the reader must consult professional books for particular cases.

MORTIFICATION (in Medicine) is the death of any tissue. It may occur from a variety of causes, as intense inflammation [INFLAMMATION], or from anything which is followed by a cessation of the circulation of blood through a part, as diseases of the arteries and veins, the pressure of tumours and foreign bodies, excessive debility, &c., or from any sudden and violent chemical or mechanical agent, as strong acids or other corrosive substances, excessive heat or cold, violent blows, &c. The process of reparation consists in the separation of the living tissues from the dead, the removal of the latter by absorption or by being thrown off externally, and the granulation and cicatrization of the exposed surface of the former.

MORTMAIN. By the 9 Hen. III. c. 36 (*Magna Charta*), it was declared that it should not be lawful for the future for any person to give his land to a religious house, so as to take it back again and hold it of the house; and any such gift to a religious house was declared to be void, and the land was forfeited to the lord of the fee. The reason of this provision is obvious, if we consider the nature of the feudal tenure; and indeed it is distinctly expressed in the preamble of the statute of the 7 Edward I., sometimes entitled '*De Religiosis*,' as follows:—"Whereas of late it was provided that religious men should not enter into the fees of any without the licence and consent of the

chief lords (*capitalium dominorum*) of whom such fees are immediately held; and whereas religious men have entered as well into fees of their own as those of others, by appropriating them to their own use and buying them, and sometimes receiving them of the gifts of others, by which means the services due from such fees, and which were originally provided for the defence of the realm, are unduly withdrawn and the chief lords lose their escheats of the same," &c. The statute then forbids any religious person or any other to buy or sell lands or tenements, or under colour of a gift or term of years, or any other title whatever, presume to receive from any one, or by any other means, art, or contrivance, to appropriate to himself lands or tenements, so that such lands or tenements come into mortmain in any way (*ad manum mortuam deveniant*), under pain of forfeiture of the same. The statute then provides, that if it be violated, the lord of whom the lands are holden may enter within a year; or if he neglect to enter, the next lord may enter within half a year; and if all the chief lords of such fees, being of full age, within the four seas, and out of prison, neglect to enter, the king may enter.

The general notion of mortmain may be collected from the words of this statute, the term being used to express lands belonging to any corporate body, ecclesiastical or temporal, sole or aggregate. Various explanations have been offered as to the reason why lands of this description were said to be in mortmain, or in *mortua manu*; that is, in a dead hand. Under the feudal system, lands held by any corporate body or person might not inappropriately be said to be in a dead hand as to the lord of the fee; for as a corporation has perpetual continuance and succession, the lord lost the profits in his lands which, under the strict system of tenures, he derived either from the services of the tenant, while alive, or from the death of the tenant and other circumstances incident to such event. Accordingly, the best explanation of the meaning of this term seems to be that offered by Coke, that "the lands were said to come to dead hands as to the lords, for that by alienation in mortmain they lost wholly their escheats, and in effect their knights' services for the defence of the realm, wards, marriages, reliefs, and the like, and therefore was called a dead hand, for that a dead hand yieldeth no service." Similarly, the old *mortuum vadum* seems to have been so called because the land in pledge was for the time dead to the pledger. [MORTGAGE.]

Before the 9th Hen. III. c. 36 was passed, a man might give or sell his lands to religious as well as any other persons, unless it was forbidden in the gift of the lands to himself; and, accordingly, the great lords, on making a grant of land, used to insert a clause preventing the sale or gift to religious and also to Jews: "*Licetum sit donatorio rem datam dare vel vendere cui voluerit, exceptis viris religiosis et Judeis.*" (Bracton, fol. 13.)*

This statute of Edward I. prevented gifts and alienations between corporate bodies or persons and others; but it was eluded by a new device, apparently invented by the clergy, and probably most used by the religious houses. These bodies, pretending a title to the land which they wished to acquire, brought an action for it by a *præcipe quod reddat* against the tenant, who collusively made default, upon which the religious house had judgment, and entered on the land.

The statute of the 13 Edward I. (Westminster, 2), c. 32, provided against these recoveries of lands obtained by collusion; for it was enacted, that after the default made, it should be inquired whether the demandant had any right in his demand or not; and if the demandant were found to have no right, the land was declared to be forfeited to the lords mediate and immediate, similarly as was provided by the previous statute of Edward I. Another provision of this statute (c. 33) furnishes curious evidence as to the devices practised for the purpose of eluding the statutes of mortmain. The words of the enactment will best explain the allusion:—"Forasmuch as many tenants set up crosses or permit them to be set up on their tenements, to the prejudice of their lords, in order that the tenants may defend themselves by the privileges of Templars and Hospitallers against the chief lords of the fees, it is enacted, that such tenements be forfeited to the chief lords, or to the king, in the same way in which it is enacted elsewhere with respect to tenements alienated in mortmain" (*de tenementis alienatis ad mortuam manum*).

Various other statutes were passed in the reigns of Edward I. and Edward III. relating to mortmain; but the next important statute is that of the 15 Richard II., c. 5. As corporations could not now acquire lands by purchase, gift, lease, or recovery, they had contrived another new device, said to be mainly the invention of or mainly practised by ecclesiastical bodies or persons. The device consisted in this: the lands in question were conveyed to some person and his heirs to the use of the ecclesiastical body or person and their or his successors. In this way the legal estate was not in the possession of those who could not legally hold it, but in a person who had such legal capacity; and the use or profit of the land, the beneficial interest in it, was secured to the ecclesiastical body or person, contrary to the spirit of the previous statutes, though not contrary to their expressed provisions. The statute of Richard, after declaring that this use was also mort-

* Viner (art. 'Mortmain'), quoting Coke, who writes this passage "*Licetum sit donatori,*" says, "Quære if it should not be *donato*, donee." Such a blunder might have been avoided by looking at the original, or might have been corrected even without doing so.

main, further declared all such conveyances to be void, and that the lords might enter on lands so conveyed, in the manner provided for by the statute De Religiosis. This distinction of the ownership of land into the legal and beneficial was undoubtedly derived by the clergy from the like distinction in the Roman law between *quiritarian* and *bonitarian* ownership, which is briefly and distinctly expressed by Gaius (ii. 40).

Though the statute De Religiosis was in its terms comprehensive enough to include all alienations to corporate bodies or persons, it is clear that this statute was mainly directed against the clergy, both regular and secular. The ecclesiastical corporations were more numerous than any other, and had been more active in getting lands into their hands. This statute of Richard II., however, expressly extends the statute De Religiosis to lands purchased to the use of guilds or fraternities, from which it has been inferred that the doctrine of mortmain had not, before the date of this statute, applied to guilds or fraternities. The statute De Religiosis is by this statute of Richard II. expressly declared to apply also to what we now call municipal corporations, and the statute places such bodies in all respects on the same footing, as to the purchase of lands, with "people of religion." If such bodies as these had been considered within the statute De Religiosis, it seems clear from the statute of Richard II. that their acquisitions of land had only recently become of such magnitude as to make it seem expedient to make a special declaration by statute as to them.

A statute of Henry VIII. (23 Henry VIII., c. 10), commonly called an Act against superstitious uses, is perhaps hardly a statute against mortmain in the strict sense of the term. The statute enacted that feoffments, fines, recoveries, and other estates, made of lands and hereditaments to the use of parish churches, chapels, guilds, fraternities, commonalties, &c., erected and made of devotion or by common consent of the people without any corporation, or to uses for perpetual obits, or a continual service of a priest, were declared to be void as to such gifts as were made after the 1st of March in the year in which the statute was passed, for any term exceeding twenty years from the creation of such uses. From the words "by common consent of the people, without any corporation," it can hardly be inferred that a number of individuals could take in perpetual succession without being incorporated, as some writers suppose; for "to take by perpetual succession without being incorporated" involves a contradiction. Nor can the statute be construed as admitting by implication such a power of perpetual succession in unincorporated individuals. The statute destroys all such estates and interests in land as in any way or by any persons were held to the use of the establishments or collections of individuals mentioned and described in the statute.

The subsequent statutes passed in the reign of Henry VIII. (27 Hen. VIII., c. 28; 31 Hen. VIII., c. 13; 37 Hen. VIII., c. 4), together with the statute passed in the first year of Edward VI. (1 Edw. VI., c. 14), put an end to religious houses and many other establishments which had been the special objects of the statutes of mortmain and superstitious uses. The consideration of what are now legally called superstitious uses properly comes under the head of USES, SUPERSTITIOUS AND CHARITABLE.

The king could always grant a licence to alien in mortmain, or, more correctly speaking, he could remit the forfeiture consequent upon alienation, so far at least as concerned himself; but such remission could strictly only affect his own rights, and not those of the mesne lords, unless they also consented. It was the practice, before the king granted his licence, to sue out a writ of *ad quod damnum*, in order that inquiry might be made and the king informed what damage himself or others might sustain from the licence. This practice however fell into disuse long before the statute of the 7 & 8 Will. III., c. 37, which authorises the king to grant to any person or persons, corporate or not, licence to alien in mortmain, and to purchase and hold in mortmain any lands or hereditaments, and that such lands shall not be subject to forfeiture. When a licence to hold lands in mortmain is granted, it generally specifies the amount in value of the lands to be held by the corporation to which it is granted, and if the corporation should be ever found to acquire lands beyond this value, such lands are forfeited to the lord.

Until the statute of 9 Geo. II., c. 36, presently mentioned, though lands could not be aliened in mortmain, yet certain gifts to corporate bodies were held good. Thus, if a feoffment was made to a dean and chapter to perform a charitable use (within the 43 Eliz., c. 4), it was good, though they could not be seised to another's use; and a devise to a college to a charitable use within this statute was also good. (Hob., 136; 1 Lev., 284.)

The statute of the 9 Geo. II., c. 36, is now commonly, though not correctly, called the Statute of Mortmain. It applies only to England and Wales. It is entitled "An Act to restrain the Disposition of Lands, whereby the same become inalienable." The provisions and object of this enactment cannot be otherwise expressed than by stating the first section at full length:—"Whereas gifts or alienations of lands, tenements, or hereditaments, in mortmain, are prohibited or restrained by Magna Charta and divers other wholesome laws, as prejudicial to and against the common utility; nevertheless this public mischief has of late greatly increased by many large and improvident alienations or dispositions made by languishing or dying persons, or by other persons,

to uses called charitable uses, to take place after their death, to the disherison of their lawful heirs; for remedy whereof be it enacted, that from and after the 24th day of June, 1736, no manors, lands, tenements, rents, advowsons, or other hereditaments, corporeal or incorporeal whatsoever, nor any sum or sums of money, goods, chattels, stocks in the public funds, securities for money, or any other personal estate whatsoever, to be laid out or disposed of in the purchase of any lands, tenements, or hereditaments, shall be given, granted, aliened, limited, released, transferred, assigned, or appointed, or any ways conveyed or settled to or upon any person or persons, bodies politic or corporate, or otherwise for any estate or interest whatsoever, or any ways charged or encumbered by any person or persons whatsoever, in trust or for the benefit of any charitable uses whatsoever, unless such gift, conveyance, appointment, or settlement of any such lands, tenements, or hereditaments, sum or sums of money, or personal estate (other than stocks in the public funds), be made by deed indented, sealed and delivered, in the presence of two or more credible witnesses, twelve calendar months at least before the death of such donor or grantor (including the days of execution and death), and be enrolled in His Majesty's High Court of Chancery within six calendar months after the execution thereof; and unless such stock be transferred in the public books usually kept for the transfer of stocks, six calendar months at least before the death of such donor or grantor (including the days of the transfer and death); and unless the same be made to take effect in possession for the charitable use intended immediately from the making thereof, and be without any power of revocation, reservation, trust, condition, limitation, clause, or agreement whatsoever, for the benefit of the donor or grantor, or of any person or persons claiming under him." The act provides that what relates to the time before the grantor's death for sealing the deed and making the transfer shall not extend to any purchase to be made really and bona fide for a full and valuable consideration, actually paid at or before the making of such conveyance or transfer without fraud or collusion. The two universities of Oxford and Cambridge, and the colleges within them, were excepted from the operation of the act; and the colleges of Eton, Winchester, and Westminster, but in favour of the scholars only, were also excepted. This act limited the number of advowsons which any college or house of learning (before referred to in the act) could hold; but this restriction was removed by the 45 Geo. III., c. 101. By the 5 Geo. IV., c. 39, the British Museum is excepted from the statutes of mortmain; and various other public bodies have been in like manner excepted by act of parliament. The judicial interpretation of this act, called the Mortmain Act, has prevented a large amount of property from being given to charitable uses. A bequest of money for charitable purposes, to arise from the sale of land, is void; or of money due on mortgages; or of money to pay off the mortgage on a chapel; or of money to build a chapel, unless some land already in mortmain is distinctly pointed out by the terms of the bequest; or of mortgages both in fee and for years; or of money to be laid out on mortgage security. This act can only be called a Mortmain Act with any propriety so far as it relates to corporate bodies, and even with regard to them with no strict propriety, inasmuch as the Mortmain Acts were intended to prevent corporate bodies holding lands to their own use, or to prevent other persons holding them to the use of corporate bodies. The act is in fact intended to limit the power of giving property for charitable purposes to any person or persons, and is very improperly called a Mortmain Act, if we consider that many gifts of land for charitable purposes were not considered, before the passing of this act, as within the old statutes of mortmain.

The history of mortmain is intimately connected with the ecclesiastical and civil history of this country. The jealousy which all mankind feel against rich and powerful bodies of men, who are combined in a perpetual brotherhood and fraternity, and the constantly increasing wealth and power of the ecclesiastical bodies in this country, doubtless contributed strongly to the passing of the enactments called the statutes of mortmain; and this, independently of the solid reasons against such bodies having large possessions, so long as the strict system of tenures continued. In modern times, when the lord can lose nothing by land being conveyed to a corporation or to a charitable use, except the remote contingency of escheat, a new notion lies at the foundation of the restraints upon such transfers or gifts of land, which, as Lord Hardwicke expressed it, was this:—

"The mischief which the legislature had in view in the Mortmain Act (as appears from the recital, and which is agreeable to the title) was to restrain the disposition of lands whereby they become inalienable." In another place he observes that "the particular views of the legislature were two: first, to prevent locking up land and real property from being aliened, which is made the title of the act; the second, to prevent persons, in their last moments, from being imposed on to give away their real estate from their families."

It will be perceived that the provisions of the act very imperfectly correspond with this explanation of its object. Thus money may be given by will (if unaccompanied with a direction to lay it out in land) to an eleemosynary corporation which is empowered to hold land in mortmain, and it may be laid out in land, or, if necessary, a licence may be obtained from the crown for that purpose. The judicial expo-

sition, that money given by will, to arise from the sale of lands, is within the act, involves a direct contradiction; it being expressly provided by the mode of donation, in the case just mentioned, that the land shall *not*, so far as the donor can prevent it, come into hands in which it will be inalienable.

The act, which is but a clumsy contrivance, and the exposition of it, are in fact directed against gifts for charitable uses; though it is probable that the notion of the impolicy of allowing lands to be forever set apart, or "locked up," had also some influence on the legislature. If this, however, had been the leading idea, a repeal of the statute which allows the crown to grant a licence to hold lands in mortmain would have been a proper addition to the act. But the legislature or the promoters of the act were apparently anxious to find out some reason or excuse for passing such an act in a country where gifts for charitable uses have been so long established and approved by popular opinion. The exceptions made in this act in favour of the universities and colleges also show that there was a party in the legislature strong enough to prevent the operation of this act being extended to those corporate bodies.

It should be borne in mind that the terms charities and charitable uses have a legal meaning very different from the popular meaning of the term charity.

The great amount of property in England and Wales which is appropriated to charitable uses, and the importance of many of those establishments which are supported by such property, render it necessary to give some exposition of the nature and administration of charities in this country, which is most conveniently done under the head of USES, CHARITABLE.

The term *Mortification* in Scotland expresses pretty nearly what mortmain does in England.

According to Stair (book ii., tit. iii., 39, ed. Brodie), "infestments of mortified lands are those which are granted to the kirk or other incorporation having no other *reddendo* than prayer and supplications and the like: such were the mortifications of the kirk lands granted by the king to kirkmen, or granted by other private men to the provost and prebendary of college kirks founded for singing; or to chaplainries, preceptories, altarages, in which the patronage remained in the mortifiers." The act of 1587, c. 29, passed in the eleventh parliament of James VI., began by reciting that the king "and his three estates of parliament perfectly understood the greatest part of his proper rent to have bene given and disposed of auld to abbaies, monasteries, and utheris persons of clergie," &c.: it further recited that "his Hienes, for the great love and favour quhilk he bearis to his subjectes, was nawaies minded to greeve them with unprofitable taxations, specially for his royal support." The act then went on to declare that it was "founde maiste meete and expedient that he sall have recourse to his awin patrimony disposed of before (the cause of the disposition now ceasing) as ane helpe maist honorable in respect of himselfe and least grievous to his people and subjectes." The act then proceeded to unite and annex to the crown (with the exceptions after specified in the act) all the lands, &c., belonging to the ecclesiastical and religious personages therein mentioned. This act was in effect more extensive than the similar acts of Henry VIII. in England.

Since the Reformation, lands given in Scotland for charitable purposes are given to the trustees of the charity, to be held either in blanch or feu holding. (Bell's 'Dict. of the Law of Scotland.')

MORTUARY, from the Latin *mortuarium*, by our Saxon ancestors called *paul-yeat*, soul-shot, or money paid at death. The mortuary was really a gift left by a man to his parish church, as a recompense for his personal tithes and offerings not duly paid. Dugdale, in his 'History of Warwickshire,' p. 679, enters minutely into the reason and original occasion of such bequests, the earliest mention of which he finds in the 'Council of Ænsham,' in the year 1009, and in the 'Laws of King Canute.' Mortuaries were afterwards distinguished into dead mortuaries, and *mortuaria viva*, or live mortuaries: the former consisting of money, or any other goods or chattels; the latter of livestock: Blount says the second-best beast, after the first had been paid to the lord for his heriot. After the Conquest we find the mortuary sometimes called a *cors-present*, because the beast was presented with the body at the funeral. John Arden, in his will dated 4th of June, 17 Hen. VIII., says, "Item, I bequeath for my mortuary, or *cors-presente*, a black gelding ambling, that Almighty God may the rather take my soul unto his mercy and grace." Dugdale quotes several ancient wills from the time of Hen. III. to that of Henry V., in which horses, caparisoned and bearing the military weapons of the defunct, are directed to be led before the corpse at his funeral, and delivered as mortuaries. This was the origin of the practice of leading horses at the funerals of persons of distinction. Mortuaries, in time, were found oppressive to the yeomanry and poorer inhabitants of parishes: they were regulated, and converted into a money payment by stat. 21 Henry VIII., chap. 6, 1530. Kennett, in the Glossary to his 'Parochial Antiquities,' says that a mortuary was sometimes paid to the lord of a fee, as well as to the priest of the parish.

(Selden, *Hist. of Tythes*, p. 287; Dugd., *Hist. Warw.*, ut supr.; Jacob's *Law Dict.*; Manning and Bray's *Hist. of Surrey*, i., pp. 386, 388; Kennett's *Paroch. Antiq.*, i., p. 101, and *Glossar.*)

MOSAIC, a description of inlaid work by which a design is produced on a surface by joining together small pieces of differently coloured substances.

Mosaic work is of great antiquity. By most authorities it is believed to have had its origin in Asia. The "pavement of red, and blue, and white, and black marble," or "of porphyry and marble, and alabaster, and stone of blue colour," in the court of the garden of King Ahasuerus (Esther, i. 6), was no doubt a pavement of mosaic work. In Greece, inlaid pavements of variously coloured marble were among the sumptuous decorations of the time of Alexander. They were for the most part probably of fret-work or geometric patterns; but among the earliest mentioned by Pliny ('Nat. Hist.' xxxvi. 60) are those *lithostrota* formed of coloured tesserae, the work of Sosos of Pergamos, whose masterpiece was the 'Unswep Hall,' a representation of the crumbs and fragments which would be found on a floor after a banquet; together with a cantharus or two-handled vase from which a dove was drinking, while others were pluming themselves and basking in the sun. By the 3rd century B.C. the art had so far advanced, that, according to Athenæus (v. 40-47), floors were laid down in the great ship of Hieron II., which were composed of small cubes of stone of every colour, so as to represent the entire history of the siege of Troy: a work, the execution of which occupied 300 workmen an entire year.

From Greece the art was carried by Greek workmen to Rome, where

it was known as *Opus musivum*, and acquired universal favour; and soon came to be applied not only to floors but to walls and ceilings. Pliny and others have left tolerably full particulars of the kinds of mosaic practised at Rome, and of the mode of working; and many specimens have come down to us. The most common kind was that composed of cubes of different coloured stones, or earthenware cemented together so as to form a regular pattern, and used for pavements. This was called *Opus tessellatum*, from the tessellæ, or tesserae, of which it was formed. Pavements of this description are found wherever the Romans settled, no less than in Rome itself—in Asia Minor, Spain, Gaul, and England, and not only in cities or large towns, as in Carthage or London, but in the remotest villages and way-side villas. Scarcely a house of any size in Pompeii appears to have been without its mosaic pavements. Specimens of these Roman tessellated pavements are to be seen in most national and local museums: the British Museum possesses several which have been found in London and various parts of England. There is, as may be supposed, a wide difference in the artistic taste and technical skill of these specimens, but their general character is the same. They consist usually of a central piece—frequently of human beings or animals—with a border or frame of a regular pattern. No attempt is made to produce refined gradations of colour or tone, or effects of light and shade; nor does it appear that the junctions of the tesserae were sought to be concealed. The whole treatment of these Roman pavements is large and simple; the work is decorative work, in

Fig. 1.

fact, not meant to be inspected minutely. Fig. 1 represents a fine pavement of this description found within the cella of a small temple of Venus at Pompeii. A more elaborate and very costly description, the true *pictura de musivo*, was that known as *Opus Vermiculatum*,

which, like the mosaics of modern Italy, was composed of extremely small cubes of marble, coloured stones, clay, or glass, and in which the *musivarii* (as the workers in the finer mosaic were called) endeavoured to 'approach as near as possible to the appearance of

Fig. 2.

painting. The immense difficulty of this kind of painting, as it is sometimes called, will be understood when it is recollected that every degree of light and shadow, and all the gradations of colour, must be produced, not as in painting proper, by the modification or superposition of hues and tints, but by the juxtaposition of solid pieces of stone or glass; and that, consequently, these must be sometimes of

an exceedingly small size, and selected and united with the utmost delicacy and accuracy. Of this kind of mosaic several very beautiful examples have been discovered. One of the most celebrated is that now known as 'The Doves of the Capitol,' which was found, with some other mosaics of great value, in the villa of Hadrian at Tivoli, and which appears to be a copy or imitation of the Cantharus and

Doves described by Pliny as the chief work of Sosos. Cardinal Furietti, who first described this work, counted 160 cubes of marble in one square inch. It was secured for the Capitol by Clement XIII. No less famous are the mosaics of the 'Rape of Europa,' found at Preneste, and now in the Barberini Palace at Rome; and that of 'Hercules delivering Hesione,' found near Arpino, and now in the Villa Albani at Naples. Some exquisite examples of this class of mosaics have been found at Pompeii; among others, the noblest yet known, a large piece consisting of many equestrian and other figures, representing, as is supposed, the 'Battle of Issus,' and which is composed of innumerable small cubes of glass. It is one of the most

admirably designed examples of Græco-Roman art extant, but the execution is not equal to the design. It was found in 1831 in the Casa del Fauno, and is now in the Royal Museum of Naples. Another very celebrated example was found in April, 1762, in the house known as the Villa of Cicero; it represents four masked figures playing on various instruments and dancing, and bears the name of the artist Dioscorides of Samos. (Fig. 2.) Of more exquisite workmanship—and in all respects a fine example of Græco-Roman art—is a mosaic representing a Choragus, or Master of the Chorus, instructing his actors in their parts, which was found in what was called from it the House of the Choragus at Pompeii. (Fig. 3.)

Fig. 3.

Another description of mosaic work in vogue among the Romans was that called *Opus sectile*, which consisted of larger pieces of coloured marble very carefully fitted together into pictures of a simple kind, something like what is now practised under the name of Florentine work: this is sometimes called *Opus Alexandrinum*, from having been first introduced by, or in the reign of, Alexandrinus Severus. Another kind, again, was executed in wood, and known as *segmentatum*.

On the decline of the Western Empire, this, like the other arts, was practised principally in Constantinople, where a school of workers in mosaic was formed, which for many centuries furnished artists for Italy, and through Italy for the rest of Europe: and, until the revival of art, mosaic was the usual method adopted for mural decoration in the churches of Italy. The Byzantine type of Christian mosaic dates from the 4th century, and continues down to the 12th, when it began to be superseded by a native Italian style. The walls and vaulted ceilings as well as the pavements of several of the basilicas in Rome and its vicinity are decorated with Byzantine mosaics of the 4th and 5th centuries. One of the best known of these is that of Santa Maria Maggiore, but the mosaics have been much repaired. An older mosaic is the representation of Christ and two Apostles, in the church of Sta. Constantia, erected by the Emperor Constantine. Some remains of the Roman school, however, seem to have lingered on, and the Christ in the church of SS. Cosmo and Damiano, of the 6th century, is believed to be quite free from Byzantine influence. Later, however, this influence was paramount, and extended even to England. Churches now mostly had in their apses a huge mosaic of Christ, his hand resting on a book, either above or surrounded by his apostles, technically called a Majesty. Some of the best examples of these are in the churches of Ravenna; but the same uncouth, expressionless, conventional type is apparent in all. By the 8th century, Byzantine mosaic had degenerated into mere rigid manufacture, carried on by fixed monastic rules, and it did not revive till the time of the Comneni in the 12th century, and then soon to relapse into its previous state. Some of the Byzantine mosaics, however, of this date have a certain splendour of effect from being of large size, and executed in vivid colours on a gold ground. The tessere of which the Byzantine mosaics are formed, are very irregular in size, and the workmanship is often extremely coarse. Many of these Byzantine mosaics are remarkable for their large amount of Orientalism of character. Among the rich examples in the cathedral of Monreale, near Palermo, in the church of San Miniato of Florence, and elsewhere, are patterns almost exactly like those found in Saracenic tracery.

One of the most remarkable mosaic works in Italy consists of the decorations, external as well as internal, of the church of St. Mark at Venice, which extend in all over some thousands of square feet of surface. For this great undertaking a very large number of Byzantine workmen were in the 11th century brought from Constantinople; and even some of the mosaics were, it is said, imported also. But native art was beginning at this time to revive in Italy, and this and other

great undertakings no doubt acted as a strong stimulus to native genius. In the 13th century, Andrea Tafi, Gaddo Gaddi, and even Cimabue and Giotto, designed mosaics, and in a newer and nobler style than the people had been accustomed to see. Italian mosaicists began to be employed upon the works of St. Mark, which were, with all the wealth of Venice, prolonged over several centuries; and eventually a native school was formed, which carried the art to its utmost perfection, so that, as Vasari observed, "it would be impossible to accomplish greater things with colours." Indeed, as Lanzi remarks, "The church of St. Mark remains an invaluable museum, where, commencing with the 11th century, we may trace the gradual progress of design belonging to each age up to the present, as exhibited in many works in mosaic, beginning from the Greeks and continued by the Italians."

Mosaic was in its most flourishing condition in the 16th century, when the Byzantine had come to be throughout Italy, with the exception perhaps of Naples, superseded by a native school. At this time the most distinguished painters—as Titian and Veronese in Venice, and Raffaele in Rome—did not disdain to make designs for execution in mosaic. But it soon after declined from its pre-eminence. Before fresco painting, in the hands of the great masters who practised it, mosaic was compelled to give way; and though it found ample patronage from the popes for the decoration of St. Peter's—the most marvellous work executed in mosaic subsequent to St. Mark's,—and has continued to be prosecuted with continued success down to the present time, it has long been employed mainly in producing copies of pictures, and not in embodying original design.

Mosaics of this kind came into vogue in the 17th century, when, in consequence of some of the frescoes of Raffaele, Da Vinci, and other great painters, having already decayed from being painted on damp walls, it was desired to have comparatively imperishable copies of them; and this kind of work is that now almost exclusively practised. In the Vatican there is a workshop devoted exclusively to preparing the mosaics of St. Peter's, and a similar establishment is maintained in connection with the cathedral of Monreale in Sicily. Mosaics of this kind are facsimiles of the original pictures, and have merely the effect of paintings produced in the usual way, although beyond all comparison more laborious and tedious in their process, and necessarily, from the nature of the process, lacking their freedom and play of hand. As each separate piece of glass is of the same colour throughout, the graduation of tints, the melting off of any one colour from its highest light to its darkest shadow, can be obtained only by an immense number of small pieces, of which those contiguous to each other exhibit scarcely any perceptible difference to the eye. It has been said that no fewer than ten thousand different tints, all of which must be kept methodically sorted and arranged, are requisite for this kind of mosaic-work; the preparation of such a palette therefore, for anything upon an extensive scale, must of itself be a task of great labour and time, as well as expense; besides which the execution is so entirely mechanical, that it is fit only for copyists. Some of the

larger and more elaborate works are said to take fifteen or twenty years in copying. The sole advantage in any degree proportionate to the cost attending it, is the extreme durability of the work when once accomplished, as its colours can hardly be changed by any length of time; nor is it liable to decay or injury, except what may happen to the structure in which it is fixed. The mosaics in St. Peter's, which are masterpieces of their kind, may be expected to last as long as the building itself stands. When Sir Christopher Wren designed St. Paul's it was his earnest wish to have the cupola decorated with mosaics, like the cupola of St. Peter's, and he had actually entered into negotiations with some Italian musaicisti for their execution, but the authorities would not give their sanction. Quite recently proposals have been issued by the present dean and chapter for carrying out Wren's intentions, according to a plan drawn up by Mr. Penrose, the present architect to the cathedral. Many tessellated pavements of good design and excellent workmanship have been laid down in this country within the last few years.

The modern Italian musaicisti have reached almost the perfection of technical and manipulative dexterity. Their mode of working differs, however, little in principle from that of the mediæval workers in mosaic. They employ for the ground of their work a plate of metal or a slab of travertine, the size of the picture, and this is surrounded by an iron frame. In this bed is spread a cement or stucco, composed of mastic, powdered travertine, and carbonate of lime, mixed with linseed oil, so as to form a paste. The tesserae, or smalti, of which the picture is composed, are imbedded in the cement, which is only laid as far as the musaicisti are ready to proceed at one time, as it remains but a short period in a fit state for working on, and eventually hardens to the consistency of stone. When the whole picture is completed the surface is rubbed smooth to remove all inequalities, and brought to a polish, or left dull, according to the position the picture is intended permanently to occupy. The smalti are of opaque glass, coloured with metallic oxides and prepared in a peculiar manner. They vary in size from an inch square to a pin's head. The mediæval mode of working and materials, will be found described in Mrs. Merrifield's 'Ancient Practice of Painting,' v. i., p. lii. &c.

Something akin to mosaic or coloured inlaid-work was occasionally employed in Italy during the middle ages for external decoration also; as an instance of which the façade of the Duomo at Pisa may be mentioned, where, though the pattern is chiefly in black and white, brilliant reds and blues are intermixed at intervals, a species of external decoration supposed by some to have been derived from the practice of *polychromy* among the Greeks. [POLYCHROMY.] This is much the character of the Oriental mosaic, of which the mosques of Cairo and Damascus afford very beautiful examples. On the resemblance between Oriental and Byzantine mosaic work, and the characteristics of the former, see 'Hessemer's Arabische und Alt-Italienische Bau-Verzierungen.'

Pietra Dura, or Florentine work, is a kind of mosaic, in which by pieces of coloured stones and marbles, figures or patterns are formed on marble slabs for tables and decorative purposes. An imitation of it is manufactured to some extent with Derbyshire marbles at Matlock, Derby, and Buxton. There is a fine sort of Florentine work, called in Italy, Pietra Commesse, which is executed with agates, jasper, and other precious stones, cut into various shapes and sizes; it is an elegant but very costly style of ornamentation.

What was called *Tarsia work*, or *Tarsiatura*, was a kind of mosaic in wood, by which landscapes and patterns were inlaid in walnut panels, by means of small pieces of wood of various shades and colours. A very humble imitation of it is the inlaid toy-work known as Tunbridge-ware.

MOSAIC GOLD. [TIN, Bisulphide of.]

MOSQUE (from the Arabic *Maschiad* or *Medsched*, and immediately the Spanish and Portuguese *Mezquita* and *Masqueta*), a Mohammedan place of worship, the distinctive marks of which are generally cupolas and minarets. [SARACENIC ARCHITECTURE.] Internally the mosques exhibit nothing remarkable as to plan or accommodation, forming merely a single large hall or apartment, without any seats or other fittings-up, and with no other decoration than that of pavements and carpets, or arabesques and mosaics on the walls. In regard to these latter, some of the mosques at Cairo are highly embellished. Although more famed than any other, the mosque of Santa Sophia at Constantinople exhibits nothing of Mohammedan or Arabian architecture, but was originally built as a church, and is in the Byzantine style. [BYZANTINE ARCHITECTURE.] The mosque of the Sultan Achmet, called the At-Meidan, at Constantinople, though of much later date, shows the influence of the Byzantine model:

we give an engraving of it as an excellent example of a Turkish mosque.

MOTET (*Mottetto*, Ital.), in Music, a vocal composition set to sacred words, and used in the Roman Catholic church. The word was synonymous with anthem, when first introduced, and signified a superior kind of hymn, accompanied only by the organ. [ANTHEM.] Latterly however the Motet has lost much of its primitive solemnity, having been, for considerably more than half a century, written with full and florid orchestral accompaniments, and thus, like the Mass, is deprived of no small portion of its devotional character. Many attempts have been made to discover whence the word is derived, but without any satisfactory result.

MOTHER-LIQUOR. [MOTHER-WATER.]

MOTHER-WATER. When any saline solution has been evaporated so as to deposit crystals on cooling, the remaining solution is termed the mother-water, or mother-liquor, or sometimes merely the mothers.

MOTION is change of place; there has been motion when a body, at one time, occupies a part of space different from that in which it was at a preceding time. The only additional necessary conception is continuity of change: every point which has moved from one point of space to another must have passed over every part of some line, straight or not straight, drawn from one point to the other.

Some of the ancients used the word in a more general sense, answering to change. Thus, according to them, creation, generation, corruption, increase, diminution, and change of place, are the six sorts of motion. We have here no further to do with this than to remind our readers, when they see *local* motion spoken of in old writings, that this is the term by which simple change of place, to which the word motion is now restricted, is distinguished from the other changes which the same word then denoted. We still apply the word, as we do terms of magnitude (see that word) to changes of the moral system, as in speaking of the motions and emotions of the mind.

If there be anything which would need neither definition nor comment, it might be supposed to be simple motion, a thing never absent from one moment of the waking perceptions, nor even of the dream. Its existence was however denied, or is reported to have been denied, by various of the Greek sophists, though it is highly probable that some matter-of-fact historians have handed down as a deliberate opinion what was merely meant for an ingenious attack on one or another established school. According to Sextus Empiricus (i. § 17), Diodorus surnamed Cronus, a Carian, disproved the existence of motion as follows:—If matter moves, it is either in the place in which it is, or the place in which it is not; but it cannot move in the place in which it is, and certainly not in the place in which it is not: consequently it cannot move at all. To which the first named author replies, that by the same rule men never die, for if a man die, it must either be at a time when he is alive, or at a time when he is not alive. A better answer would have been, that it is true of all material phenomena that they happen either in the place in which the matter is, or in that in which it is not, except only the change from that place in which the matter is and will not be, to that in which it is not but will be. The syllogism of Diodorus may be useful to remind us that motion implies both spaces and times, since the sophism excludes the latter from consideration. Zeno of Elea (not the Stoic) gave the celebrated argument of Achilles and the Tortoise. [PROGRESSION.]

If we consider merely motion, without any reference to the matter moved or the quantity of external force required to move it, we have, as we conceive, a subject of pure mathematics before us, though this has been contested. Newton however used considerations of motion without hesitation in his fluxions; and his successors have endeavoured to avoid them by circumlocutions, which, however consonant they

motion along BC , while BC itself is carried into the position ED ; that is, B will appear to move along the line BD , the spectator imagining himself to remain at O . The dotted lines show the method of proceeding, as first described.

While a ship A (*fig. 3*) moves from A to B , let C move through CD

Fig. 3.

(CD being equal and parallel to AB), E through EF (EF being parallel to and equal to one-half of AB), G through GH , K through KL , M through MN , and let P remain at rest. Then, a spectator in A supposing himself at rest, C will appear to remain at C , E will appear to move through Ef , G through Gh , K through Kl , M through Mn , and P through Pp . The motion of A has been transferred in a contrary direction to each of the other vessels.

When bodies are very distant their changes of distance are not soon perceived, consequently it is only by change of direction that their motion becomes visible. This is the case in all the heavenly bodies; but we shall now show what the apparent motion of a planet, superior and inferior, would be, if changes of distance, as well as direction, could be perceived and estimated.

If the spectator be in motion, an object at rest appears to him to have precisely his own motion, but in a contrary direction; for if the object be O and the spectator move through $ABCD$, no distances would

Fig. 4.

be changed if the spectator were fixed at O , and the object moved through $ABCD$, and all directions would only undergo a diametrical change. Consequently the relative motion of the object is represented by allowing it to change places with the spectator, and inverting the direction of north and south, which will have the effect of making the relative motion from west to east, if that of the spectator were from east to west, and *vice versa*. Let us suppose now that the earth moves round the sun in a circle, which will be near enough for our present

Fig. 5.

purpose; it will be immediately obvious that the direction of motion, so far as concerns the order in which constellations will be described, is the same in the relative motion of the sun round the earth as in the absolute motion of the earth round the sun. For though the absolute directions of motions are opposite, yet S , to a spectator at E , is seen towards a point of the heavens opposite to that in which E appears from S . [MOTION, DIRECTION OF.]

In giving to the sun the apparent motion which answers to the real motion of the earth, the same motion must be given to the orbits in which the planets are carried round the sun. The question then is as follows:—If a planet move round the sun, say with a uniform circular

motion, while the sun moves round the earth, also uniformly and circularly, what path will the planet actually trace out?

To get a notion of the possible species of curves, let us simplify the question by supposing a circle $ABCD$ moving along a straight line ET , while a point moves round the circle from A .

Fig. 6.

In the first place, if A did not move round at all, the line AG would be described; if A moved slowly round, the translation of the circle would cause an undulating curve like AHK to be described; if A moved as fast on the circle as the circle itself is moved forward, the undulation would be changed into a curve with cusps like ALG ; while if A move faster on the circle than the circle is carried forward, the circle, so to speak, will not have time to get out of the way, and prevent the formation of loops, as in $AMNMPQRQ$. The faster A moves, the larger and the nearer will be the loops, so that at length no one will be clear of the preceding and following, or the loops will interlace.

If the circle move round another circle, the same appearances will be presented in an inverse order. Let the centre E of the circle $ABCD$ (*fig. 7*) be carried round the circle ET , whose centre is O . If A did not move at all upon its circle, it would, by the motion of its circle, describe a circle (dotted) equal to ET ; if A moved slowly, it would describe a succession of close loops enveloping O ; if quicker, the loops would at last disengage themselves from each other; while for still more rapid motion of A the loops would become cusps, and afterwards the curve

Fig. 7.

would simply undulate. The character of these curves will be further discussed under TROCHOIDAL CURVES, and their astronomical application under PLANETARY MOTIONS. It is sufficient here to say that the apparent orbits of all the planets (or rather, the orbits as they would be if changes of distance were perceptible) are trochoidal curves of the above-described species, with loops which do not interfere with one another.

The composition of motion has been virtually proved in the preceding paragraphs, combined with the account of the second law of motion. [MOTION, LAWS OF.] If causes of motion act instantaneously, one of which would make a body describe AB (*fig. 8*) uniformly, and the other

Fig. 8.

AC , in the same time, we find in the second law of motion that the body will move so that its distance from AB at the end of any time, measured parallel to AC , is what it would have been if the cause of motion in the direction AB had never existed nor acted. Suppose, for example, that three-fifths of the whole time of motion from A to B has elapsed; take AD three-fifths of AC , and the body must be then somewhere in the line DE . Again, take AF three-fifths of AB , and by the same law it follows that the body must be in the line FG ,—that is, it must be at the point H , which simple geometry shows to be on the diagonal AK , and by three-fifths of that diagonal distant from A . The same may be shown for any other proportion of the whole time; consequently the body, impressed with the two motions, describes the diagonal AK uniformly, and in the same time as that in which the separate motions,

from A to B, or from A to C, would have been performed. This is precisely the course the body would have taken in space, if, while it moved from A to B on the paper, the paper itself had taken the motion A C; but the establishment of the latter assertion must not be confounded with the proof of the composition of velocities impressed on matter; the latter requires those considerations which lead to the second law of motion.

There are a great many uses of the word "motion," which are convenient, but require the introduction of arbitrary suppositions. Thus the moon never cuts the ecliptic twice running in the same place, and the intersection of her orbit with the ecliptic being called a node, it is said that the *node moves*, thus giving this node a sort of imaginary existence in the interval.

MOTION, APPARENT. [MOTION.]

MOTION, DIRECTION OF. We have inserted this article, not for the sake of rectilinear, but of circular motion, the consideration of which is apt to cause some embarrassment to the beginner. In motion along a given right line there can be but two directions, in one or other of which the course must be; and these two directions are opposite to one another. But in circular or other rotatory motion, all imaginable directions are taken in the course of a revolution, and whatever linear direction the moving body takes at any one point, it has the opposite direction at the opposite point. Still, however, there are two ways of moving on a circle: the motion may either be from C to A through B, or from A to C through B. These are called, somewhat improperly, different directions of motion.

If two bodies be moving over two circles, they are said to move in the same direction when, two radii being taken in the same direction, the linear directions of motion are the same, as B D and Q R. Thus care must be taken not to compare two circular motions by positions which belong to radii in opposite directions. If, for instance, the directions of motion be A B C and Q V S (which are the same), and if at the same time the two bodies be at B and S, their linear directions of motion are opposite, though according to the definition their circular motions are in the same direction. Thus, in the case of the moon, and her revolution round her own axis [MOON], the middle point of the visible moon is moving round the moon's axis in a direction opposite to the orbital motion of the moon; but the radius of that middle point is opposite in direction to the line joining the centres of the earth and moon; so that the direction of revolution of the moon's rotation is the same as that of the orbital rotation.

MOTION, LAWS OF. The laws of motion mean those universal methods of receiving and losing motion which close attention to mechanical phenomena, coupled with strict inductive reasoning, has shown to be inherent in the constitution of matter.

If an intelligent observer, not used to inductive reasoning, nor instructed in the results of mechanics, were required to state the views which experience had taught him of the constitution of matter, as an agent or patient in the production or reception of motion, he would perhaps reply as follows: Matter seems to have no power of moving itself, though if we judge from the fall of bodies towards the earth, the phenomena of magnetism, &c., it would appear as if matter might be the cause of motion in other matter. And it seems moreover that motion is an accident of matter which diminishes and dies out of itself, if some sustaining cause be not perpetually in action; for in all cases in which the experiment can be tried, we find that moving bodies are reduced to rest by being left to themselves. The motions of the heavenly bodies, it is true, appear to be permanent; but we have no certain assurance that there is not a constant sustaining *physical* cause of this permanency.

There would be something of truth, and a good deal of falsehood, in the preceding conclusions, and it is not an easy thing to give that exhibition of the real constitution of matter which is placed beyond all doubt by the coincidence of its results with all the more complicated phenomena of nature. There is no question that those principles, to take two cases out of thousands, on which a ball can be projected almost unerringly to its mark from the mouth of a cannon, and the motions of the moon can be predicted within a small fraction of a second, are founded in truth; but it does not therefore follow that an *a priori* demonstration of them, mathematical or experimental, can be given; and in fact the method of presenting the laws of motion to a beginner is encumbered with serious difficulties.

We shall begin by the assumption that those laws of motion which

are to be found in all works on mechanics are true; the reason for such assumption being, that if we take them for granted, and use them as the basis of a mathematical system of mechanics, all results of that system, however many the links in the chain of deduction, are found to agree with observed phenomena in species, and as nearly in magnitude as the various resistances and disturbances will allow. In astronomy and optics, phenomena have been predicted with all but geometrical accuracy, by deduction from principles which would certainly be false if the received laws of motion were false. In terrestrial mechanics, the number of instances is unlimited in which these laws lead to that near approximation to prediction which is fully as much as can be expected with our imperfect knowledge of data. Many hundreds of phenomena admit, upon these laws, of an explanation which, compared with that which they could receive from any others, is as easy as the hypothesis of the motion of the earth compared with that of its stability.

So simple are the laws of motion themselves, that many have supposed them to be necessary, in the same sense as when we say it is a necessary consequence of our conception of straightness that two straight lines cannot inclose a space. We shall mention this notion again presently: in the meanwhile we are in this situation, that while it is difficult, as a matter of reasoning, to disentangle the fundamental laws from the variety and complication of the phenomena in which their effects are exhibited, yet these laws themselves, when disengaged, are of that startling simplicity which disinclines the mind to receive them as the results of a train of deduction, and disposes it rather to think that it could have dictated them from its own previous conceptions.

It will make some difference in our method of seeking for these laws, whether we suppose the earth to be at rest or in motion. Now the decisive proofs of the motion of the earth, as it happens, are themselves derived from certain consequences of the laws of motion. [MOTION OF THE EARTH.] We seem then to be reasoning in a vicious circle; nor do we see any mode of escape except by establishing the truth of these laws, whether the earth be at rest or in motion. And the process will be, first to detect laws for which there is a high and almost overpowering degree of probability in their favour; next to appeal to the above-mentioned uniform truth of the results deduced from the assumption of such laws for the conversion of this high state of probability into one of absolute demonstration.

We will first assume the motion of the earth: every point of its surface then is in a state of revolution round the axis, while at the same time the whole is carried forward round the sun; to which we must add, the slight motion arising from the precession of the equinoxes, and the possible translation of the whole system. But this motion is very different in different parts; at the pole, for example, there is no diurnal motion, near it only a small one; and at the equator a considerable one. The points near the pole, all the motions considered, are describing a trochoidal orbit, the undulations of which are small, and the rotatory velocity small; those near the equator make larger undulations, with greater velocity of rotation. Our first idea might be, then, that at the different parts of the earth some modification of general laws would be observed, arising from the difference of the motions of the several places. It would not surprise a person wholly unacquainted with mechanics, to whom the preceding facts were stated for the first time, if he were told that some mistakes were made in the pointing of guns in our Indian battles, arising from the artillerymen having been trained by officers who had learnt their art in the latitude of Addiscombe, near Croydon, in Surrey, and had forgotten to allow for the difference in the diurnal motion of the two countries. Now the considerations which tend to establish the Second Law of Motion depend upon the fact that it never has been found necessary to take any notice of the difference of place on the earth in estimating effects of motion. It is not found necessary to write different treatises on gunnery for different latitudes, nor to alter the disposition of parts in any machine moved from one latitude to another to produce a more advantageous effect. There is, it is true, a small diminution in the weight of bodies, as they are carried toward the equator, and [CENTRIFUGAL FORCE; PENDULUM] the results of this are apparent in experiments in which the acquisition of motion depends upon weight, or rather, upon its proportion to the quantity of matter. But this very problem of the pendulum is one in which the question of the truth of the laws of motion is established by a test which would detect the smallest quantities, and furnishes an answer to those who might say that the possible effects of the difference of diurnal motions, though not distinguishable in such cases as that of a cannon-ball, might be perceptible in delicate instruments.

If to the motion of the earth we superadd another, such as the motion of a carriage, the same sort of result is found. Those who move on a railroad at the rate of 30 miles an hour, or 44 feet in a second, do not find the relation in which they stand to the objects in the carriage in any degree changed by the motion. At the instant of taking the motion, or on any sudden jolt or change of motion, effects may be produced to which we shall frequently refer: but when the speed is once obtained, it is well known that a person might occupy himself in reading a work on mechanics written on *terra firma* (so called), and might verify all the experimental conclusions, without coming to any result which would remind him of the difference of

state between the writer and himself, as to motion. Hence we are led to the conclusion that all the relations of matter to matter remain unaltered, if the whole system be made to move, provided that the same motion be communicated to all its parts. And though we do not, absolutely speaking, know what rest is, since no point of the earth, nor of any heavenly body, can be shown to be at rest, yet since we see that the relations remain unaltered when the velocity of a whole system is changed, we are led to conclude that the same laws which prevail when all the parts of a system have the same motion, would also prevail if the whole system were at rest; the ground of our presumption being, that the laws remain unaltered under any alteration of the common motion which it is in our power to make.

Let us now suppose that the carriage, instead of moving in a right line, is carried on a curved road, say a simple circle. It is no longer observed that loose objects in the carriage have a tendency to repose relatively to the carriage itself. If the motion become sufficiently rapid, or the friction of the substances on which they stand be sufficiently small, they will endeavour to move outwards, or from the centre of the circle of motion. This phenomenon can be made a consequence of the laws of motion, when the latter have obtained their simplest form; we do not at present enter into this subject further than to point out that it is only of rectilinear motions we can predicate any law as descriptive of what is inherent in matter. We have, it is true, already spoken of circular motions in taking into account those of the earth; but it must be remembered, firstly, that the circles in question are so large, that a small arc of any one is nearly a straight line; secondly, that we have been obliged to advert to this tendency outwards, which is the reason of the diminution of weight (or of much the greater part of it) detected from the oscillations of a pendulum which is carried towards the equator.

This second law of motion (for such it is called, though it must be deduced first when the earth's motion is considered) may be thus stated:—If there be two or more causes of motion, taking place in two different right lines, whether inherent in the body or external to it, their effects do not interfere, nor does either diminish or augment the effect of the other. If, for instance, the body A be subject to two

actions, one of which, being entirely in the direction AB, would bring the body to B in a given time, and the other, entirely in the direction AC, would bring it to C in the same given time; then the body will move from A to D, precisely as it would have done if, moving along AB in the manner first specified, the line AB had been translated with its extremity A moving in the second manner specified, the said line AB not changing its direction.

The most simple and general method of stating this law is as follows:—The distance of a point from a straight line or plane, measured in any given direction, and as it will be at the end of a given time, is not affected by the action, during that time, of any causes of motion, provided they act in the direction of, or parallel to, that straight line or plane; or no force, in a given direction, can produce motion to or from a line in that direction. Thus if a ball were thrown up in still air, in such a manner that it would mount 50 feet in one second, no imaginable horizontal current or whirlwind, however much it might alter the actual course of the ball, would prevent its rising 50 feet in the second. The statement of the law by Newton, namely, that when a force acts upon a body in motion, the change of motion which it produces is in the direction and proportional to the magnitude of the force which acts, is perhaps rather too vague to give a distinct notion to learners.

From the law just enunciated, we may learn that bodies upon the earth, moving with the earth, have the properties of bodies at rest with respect to all motions that are to be estimated relatively to the earth: at least upon the supposition that the curvature of the motions of the earth is not sufficiently great to produce a sensible effect. We have then to inquire what is the natural state of matter on the earth? Can it preserve any motion of itself, or does every motion gradually slacken and die out, by the mere inability of matter to maintain it without the application of external causes? On this point we have only strong presumptions, which would be by themselves insufficient. Our first step would be to conclude, from what we actually see, that rest is the natural state of matter, and one to which it always approaches, however great a cause of motion be applied, unless that external cause, or some part of it, be maintained. On looking further however we find that terrestrial matter, immediately on its being put in motion, encounters causes of retardation. The resistance of the air, and the friction of the basis on which the substances rest, are easily shown to lessen the motion of bodies which encounter them. The more nearly these are removed, the longer does motion continue. It is certain then that these resistances contribute in a great degree to the destruction of motion; but it is not therefore to be immediately assumed that there

is no other cause. If we grant that a perfectly smooth ball, lying upon an indefinitely extended plane without friction, and not in contact with any atmosphere, would move for a long time without any sensible diminution of the rate with which it was made to set out, we grant quite enough to explain all that we see, without the necessity of supposing that the motion would continue for ever. How then can we establish the first law of motion (so called), which is thus stated, that matter will retain its state of rest, or of motion, for any length of time, however great, until acted upon by some external cause? We must here appeal to the results of the application of this law, which have never, in any one instance, exhibited any reason to suspect that it is only approximately true. Throughout the long period of astronomical history, no one of the heavenly bodies has shown any diminution of its motion, or any of the consequences which would arise if the motion had a tendency to wear itself out. We shall not here go into the details of these consequences; the conclusion is, that the state which matter, independently of external bodies, has been created capable of maintaining, is not merely rest, but also uniform motion in a straight line; so that it has no more tendency of itself to part with any of its velocity, nor to move slower or faster than it was first made to move, than it has to set itself from rest into motion. A great many, perhaps most, of the mistakes which have been made by writers against the Newtonian theory of attraction, have arisen from want of proper conception of the *neutral state* of matter. Maintenance of velocity and direction has been to them a proof of the existence of external causes maintained in action; whereas it proves nothing, but that there was at some time or other an external cause which acted for a longer or shorter time: the external cause steps in when the velocity changes, or the direction, or both, and not till then.

Properly considered, the immense number of different states which matter retains, namely, either absolute rest, or any degree of velocity whatsoever, is as wonderful and mysterious a law as that of the attraction of matter upon matter, without any apparent intermediate agent. That matter should, without any perceptible maintainer, keep one rate of motion and one direction until acted on from without, is as difficult to admit, as that the mere presence of other matter should change that motion and that direction. What should teach blind atoms to draw straight lines in preference to circles or spirals? Have they the fundamental conceptions, according to some, or the powers of perception and inference, according to others, by which reasoning minds know or discover the simplicity of a straight line?

These two consequences of observation, namely, the law of its existence, by which matter can retain certain states, if no other matter interfere, and that by which it can change the state of other matter, its own at the same time undergoing another change, should never be allowed to be separated. There are two classes of philosophical speculators (for no religious question need be allowed to enter), whose system introduces no difficulty into the details of mechanical philosophy which did not enter into its principles. The first consists of those theists who look upon the maintenance of the creation to be the consequence of the same power as that which first created, and who consider that one moment's cessation of a sustaining power, of the same quality, so to speak, as the creative, would be the annihilation of all things: the second consists of atheists, who will of course find no more difficulty in the maintenance of the universe than in its first construction. But a great confusion of ideas is introduced into all fundamental questions which relate to matter, by the existence of a sect which we suspect greatly to outnumber either of the former two, and whom we may call believers in the *Creator* and not in the *Maintainer*. These, whatever they may think of the God of the moral world, imagine that the God of the material became inactive and quiescent as soon as matter was created, and endowed with certain powers, or made subject to certain laws. These laws, which are really their minor deities, carry on the business of the universe, and they can abstract the idea of God altogether from the continuance of the existence of matter, though not from its first creation. Among them may be found many of the literal interpreters of the Mosaic account [MOTION OF THE EARTH], who hold strictly that the Creator "rested from his work," and left matter to its "laws," except on certain rare interpositions. Many of this sect have admitted the laws of motion, and, among others, the power of matter to maintain its motion, because there was an appearance of inactive sameness, or want of change, in the permanence of rest, or permanence of direction and velocity. But they have been startled by the entrance of attraction, and have disputed its possibility on account of the absence of *second* causes sufficient for its explanation: however clearly it might be shown that all the results of attraction are present among phenomena, they would not allow their *first* cause to be awakened from the sleep in which it was their pleasure to suppose him plunged, so far as matter was concerned. Perhaps it is one of the most singular mental aberrations which ever was manifested, that at the time of the appearance of the Newtonian doctrine, the first mechanical theory which rested on the *maintainer* of the creation, at least until (which has not yet happened) some good quiescent "second" cause was discovered—that doctrine was frequently charged with atheism.

If the earth were supposed to be fixed, we might obviously (though not obliged to do so) begin from matter at rest, and establish first that law of motion which usually stands first.

The third law of motion was enunciated by Newton as follows:—"Action and reaction are equal and *opposite*." Thus, if a body A exerts a force upon another body B by contact, tension, thrust, attraction, repulsion, or otherwise; then B exerts the very same force on A in the opposite direction. The principle thus laid down belongs as much to statics as to dynamics, and is not therefore to be considered a special law of motion. It seems indeed to establish a relation between the statical and dynamical effects of a force—the action being represented by the pressure employed, the reaction by the motion produced. But how is this motion to be measured? Newton had decided that a body's motion should be measured by its momentum, and enunciated the third law on this supposition. But taking as we now do the velocity generated in a body to be the dynamical measure of the force,—that is, the reaction,—the third law of motion asserts that "the velocity generated in a body by the *action* of a force, whether impulsive or otherwise, is proportional to the force."

Where the force continues to act during a finite interval of time, the body acquires an additional velocity in each succeeding instant—an evident consequence of the second law of motion. The velocity thus generated in a unit of time (as one second) is termed by some modern writers the "rate of acceleration." And this is all that is meant by the expression "accelerating force,"—namely, a force that, acting continually upon a body, produces in it a rate of acceleration. Thus the force of gravity is called an accelerating force, because the motion of a body, under its influence, becomes accelerated; the rate of acceleration being about 32.2 feet per second. [ACCELERATED MOTION.]

Let f and f' denote the rates of acceleration produced respectively by the action of two forces F and F' ; then, by the third law of motion, $f : f' = F : F'$. Also, if t be the time during which these forces act, v and v' the respective velocities acquired at the end of time t , we have $v = ft$ and $v' = f't$, hence $v : v' = F : F'$. If a body move under the action of gravitation, the rate of acceleration is g ($=32.2$), hence if F act upon a body whose weight is w , we have the following very useful application of the third law of motion:—

$$F : w = f : g$$

or,

$$F : w = v : gt$$

when v = velocity acquired in time t by the action of F .

The three laws of motion, then, may be thus enunciated:—

1. A body, if acted upon by no external force, remains at rest; or if in motion, continues to move uniformly in the same direction.
2. When any number of forces act upon a body in motion, each force produces the same effect in altering the magnitude and direction of the body's velocity, as if it acted singly on the body at rest.
3. The velocity generated in a unit of time by a force continually acting upon a body, is proportional to the force.

The reader will meet with some very clear conceptions of the three laws of motion in Dr. Young's 'Natural Philosophy,' edited by Professor Kelland; also in O'Brien's 'Natural Philosophy,' published by the Society for the Promotion of Christian Knowledge. He may likewise refer to a paper by Dr. Whewell "On the Nature of the Truth of the Laws of Motion." ('Camb. Phil. Trans.' vol. v. part ii.)

The mistakes into which philosophers fell upon the laws of motion are uninteresting except in the applications which were made of them; and in the article MOTION OF THE EARTH will be found enough of these to give an idea of the difficulties which such fallacies placed in the way of sound knowledge. For an account of Galileo's labours, see GALILEI, in BIOG. DIV. For an account of the notions of Descartes on the same subject, see VORTICES. The first distinct enunciation of these laws appears in the Principia of Newton.

Though all mechanical problems admit of solution upon the assumption of these laws, in conjunction with those which may be called the distinctive properties of the solid, fluid, and gaseous states, yet the purposes of mechanical inquiry are better served by certain general principles deduced from them, the proper conception of which can only be made by mathematicians, and are therefore referred to a purely mathematical article—VIRTUAL VELOCITIES. [PRESSURE, FORCE, INERTIA, CENTRIPETAL AND CENTRIFUGAL FORCES, ACCELERATED MOTION, VELOCITY, &c.; MOVING FORCE. See particularly the article INERTIA, for the reason of the non-introduction of that word.]

Among the many absurdities which have arisen out of a misapprehension of the laws of motion, is the attempt to discover what is called a *perpetual motion*, or a machine which of itself would never stop. The earth and planets are such machines in their rotations on their axes; and we have seen that any particle of matter, unacted on by other matter, and once in motion, is a perpetual motion. If a wheel attached to an axle could be deprived of friction at the pivots, and enclosed in a permanently air-tight and perfectly exhausted receiver, it would also, when once in motion, be a perpetual motion. But as long as any friction or resistance, however small, is perpetually retarding the motion, it is obvious that the velocity, if maintained, must be indebted to some external supply of moving power. To take the case of friction, which arises from the roughness of the supports, and which, independently of *adhesion*, may be considered as a rapid succession of very small jolts, by which the roughnesses of the one surface strike upon those of the other, and communicate a portion of momentum to the frame, and finally to the earth: to suppose that a wheel as above

described could go on for ever, with friction, would be to suppose that there could be action without reaction. In fact, a perpetual motion, such as is intended to be made by the speculators on the subject, is nothing less than a machine which will work for ever without new moving power; it being not one bit less absurd to suppose that it would perpetually overcome friction and atmospheric resistance, than that it would continue to supply the impetus necessary to carry on the sawing of a plank or the weaving of lace.

MOTION OF THE EARTH. The theory of gravitation has placed this question on a footing entirely different from that on which it was argued, whether by Ptolemaists or Copernicans. Both of the latter parties supposed the existence of a fixed central body somewhere, which the first of them would have to be the earth, and the second the sun. This *centrum mundi*, or centre of the universe, is exploded, and with it all the systems, whether Ptolemaic or Copernican, which preceded the discoveries of Newton. But, as noticed in COPERNICUS, in BIOG. DIV., the existing system preserves the name of that great man; the reason being, that its distinctive peculiarity is retained relatively, if not absolutely, namely, that the planets all move round the sun, or round a point near the sun. But it is added to the real Copernican system, that sun, planets, and all, may be, and probably are, in motion; the translation, as it is called, of the whole system being very nearly rectilinear, and the curvature, if any, arising from the attraction of the fixed stars. Nothing but a long course of observation can settle this last part of the question, though much has been done of late years to establish the affirmative.

In approaching the old controversy on the motion of the earth, we confine ourselves rather to the arguments by which it was opposed than to those by which it was supported. For this we have two reasons: first, that the latter are well known and extensively circulated, while the former, unless preserved in historical articles, will find the oblivion from which they have no intrinsic merit to rescue them; secondly, that the controversies of the present day may be usefully illustrated by recurring to the long-decided struggle between the Copernicans and their opponents. We have now among us those who would fetter all *new* truths by *their* interpretation of the Scriptures, though they quietly acquiesce in the defeat which their own principle formerly received. The charges still brought against the cultivators of the sciences, "to the distress and disgust of every well-constituted mind," as Sir J. Herschel expresses it, should be looked at, not as the honest manifestations of an alarm newly awakened by the circumstances of the present day, but as the effects of an abiding spirit, which has always opposed investigation, and which, if it had prevailed, would have smothered all the knowledge of nature which has been acquired in the last two centuries. If some of those who have constituted themselves successors to the cardinals who forced Galileo to recant, have learnt from the past history of their own cause, and from the temper of the present age, to show the real scope of their system less openly than it appeared in the 17th century, the compliment which they thus pay to the advancing intelligence of mankind, though received with thanks and highly appreciated, should not be accepted as an equivalent for the mischiefs which must result from a successful attempt to place the great question of Revelation upon a false basis. The case of those who now endeavour to impede the progress of geology, or to limit speculation on the *process of creation*, is so similar in its fundamental points with that of the labourers to the same effect in the field of astronomy, that the circulation of some account of the latter will perhaps enable our readers to help themselves in forming their opinion of the former.

When the work of Copernicus appeared in 1543, it seems to have been considered as a mere attempt to demonstrate (see the old use of this word in DEMONSTRATION) the motions of the heavenly bodies in a more simple way. Guarded as it was by the expressions of the preface, it was neglected as a purely speculative trial of a strange and impossible hypothesis. In 1566 Ramus ('Scol. Math.') simply reproaches Copernicus with the gigantic character of his hypothesis, and says it would have been better to have taken one nearer to the truth, in a manner which implies that he thought both were agreed as to what the truth really was. Copernicus himself, as we have seen, treated his own ideas as a reproduction of those of the ancients, and in truth the existence of such a doctrine as the earth's motion was perfectly well known to all men of learning. Aristotle (in his second book on the Heavens) states that Pythagoras and his followers placed the sun in the centre, on account of the superior excellence which they attributed to the element of fire, of which they supposed the sun to be made. Different authorities give the same opinion (whether with or without the reason) to Philolaus, Anaximander, Nicetas, Seleucus, Cleanthes, Leucippus, Ecphantus, Heraclides Ponticus, and Aristarchus. The introduction of Pythagoras, as a predecessor of Copernicus, is as rational as would be the connection of the modern atomic theory with the doctrines of Epicurus; and much of the same kind is an assertion not unfrequently made, that Cardinal Cusa was a supporter of the earth's motion. This writer ('De Doctâ Ignorantiâ,' lib. ii., c. 11) certainly denies that there can be any centre of the universe; for, says he, if there were a centre, there would be a circumference, that is, a termination, to the universe; and his reasons relative to the earth's motion are of the same degree of force. He is more rational in the next chapter, where he explains that the apparent motion of other

bodies may be that of the spectator. Riccioli cites a sermon of Cusa, which proves, says he, that the cardinal had come to a sounder opinion; for he speaks of God's angels or intelligences moving the sun and stars. Nothing can better illustrate, in our opinion, the arguments against Riccioli and his predecessors: when the cardinal is writing for men of science, he advances, after his fashion, speculation about the earth's motion; when he is writing *excitations* (not *exercitations*, as Riccioli says) to religious feeling, he speaks of God's works in a manner which persons in general understood; in confounding the preacher of religion with the philosopher, Riccioli made the usual error of his day, and only repeated his own mode of treating Moses, Isaiah, and the writer of Job. But it would have been better to have argued by analogy, that if either of the latter had written a professedly philosophical work, he might, whatever appears to the contrary from his religious writings, have admitted the motion of the earth.

Copernicus had no predecessor as a mathematical reasoner upon the question. The first continental followers of the new system were Rheticus, Reinhold, Mästlinus the instructor of Kepler, and Urstitius who was probably the instructor of Galileo. In 1556 appeared in England the 'Castle of Knowledge,' by Recorde [RECORDE, ROBERT, in BIOG. DIV.], in which a cautious and implied avowal of Copernican principles is made, and also the Ephemeris of John Field, expressly computed from Copernicus and Reinhold. John Dee and his pupil Thomas Digges (son of Leonard) were both avowed Copernicans: the first absolute defence of the system is contained in the Appendix to the 'Prognostication Everlasting,' &c., of Leonard Digges, republished by Thomas Digges (who added the Appendix) in 1594. This Appendix is called 'A Perfit Description of the Coelestial Orbes, according to the most ancient Doctrine of the Pythagoreans; lately reuiued by Copernicus, and by Geometricall Demonstrations approued.' We shall quote from this work the account (in modern spelling) of "what reasons moved Aristotle and others that followed him to think the earth to rest immoveable as a centre to the whole world."

"The most effectual reasons that they produce to prove the earth's stability in the middle or lowest part of the world is that of Gravity and Levity. For, of all other, the element of the earth (say they) is most heavy, and all the ponderous things are carried into it, striving (as it were) to sway even down to the inmost part thereof. For the earth being round, into the which all weighty things on every side fall, making right angles on the superficies, pass to the centre, seeing every right line that falleth perpendicularly upon the horizon in that place where it toucheth the earth, must needs pass by the centre. And those things that are carried towards that medium," or middle point, "it is likely that there also they would rest. So much therefore the rather shall the earth rest in the middle, and (receiving all things into itself that fall) by his own weight shall be most immoveable. Again, they seek to prove it by reason of motion and his nature; for of one and the same simple body the motion must also be simple, saith Aristotle. Of simple motions there are two kinds, right and circular: right are either up or down; so that every simple motion is either downward toward the centre, or upward from the centre, or circular about the centre. Now unto the earth and water, in respect of their weight, the motion downward is convenient to seek the centre; to air and fire, in regard of their lightness, upward and from the centre. So it is meet to these elements to attribute the right or straight motion, and to the heavens only it is proper circularly about this mean or centre to be turned round. Thus much Aristotle. If therefore (saith Ptolemy of Alexandria) the earth should turn but only by that daily motion, things quite contrary to these should happen. For his motion should be most swift and violent, that in twenty-four hours should let pass the whole circuit of the earth; and those things which, by sudden turning, are stirred, are altogether unmeet to collect, but rather to disperse things united, unless they should by some firm fastening be kept together. And long ere this the earth, being dissolved in pieces, should have been scattered through the heavens, which were a mockery to think of; and much more beasts and all other weights that are loose could not remain unshaken. But also things falling should not light on the places perpendicular under them, neither should they fall directly thereto, the same being violently in the meanwhile carried away. Clouds also and other things hanging in the air should always seem to us to be carried toward the west." In his answer to the preceding, Digges propounds the experiment which was afterwards urged (by those who had not tried it) against Copernicus, as follows: "Of things ascending and descending in respect of the world, we must confess them to have a mixed notion of right and circular, albeit it seem to us right and straight, not otherwise than if, in a ship under sail, a man should softly let a plummet down from the top along by the mast even to the deck: this plummet passing always by the straight mast seemeth also to fall in a right line; but being by discourse of reason weighed, his motion is found mixed of right and circular." From his preface Digges appears to have considered magnetism as the cause of the earth's self-sustaining power; an opinion carried further by Gilbert (the next English Copernican) in 1600, who, in his book on the magnet, endeavours to deduce the earth's motion from magnetic causes, as well as the precession of the equinoxes.

The period from 1543 to 1609, in which the controversy was purely mathematical, has not excited the interest which every one knows to

belong to the consequences of Galileo's discoveries. An account of this period is to be found in the 'Companion to the Almanac' for 1855, in 'Notes on the Ante-Galilean Copernicans.' To this article we must refer the reader for further account, in connection with this subject, of Leonardo Da Vinci, Calcagnini, Widmanstadt, Copernicus, Rheticus, Gassarus, Rheinhold, Ramus, Maurolycus, Bacon, J. B. Benedictus, Tycho Brahé, Rothmann, Stunica or Zuniga, Francis Patricius, Urstitius, Gilbert, E. Wright, Clavius, Vieta, Mästlinus, Bruno, Ursus Dithmarsus, Maginus, Stevinus, Kepler, Recorde, Field, Digges, Dee, Blagrove, Lydiat, Hume.

Hitherto the theological part of the controversy has not made its appearance. We must date this view of the question from the discoveries of Galileo. Neither in ancient nor modern times have those who would bind over the sciences to agree with *their* interpretation of the Scriptures ever taken alarm at hypotheses, until those hypotheses began to have facts in their favour. The inconsistency is worth noting; for, taking these objectors on their own principles, there may be impiety (if the Bible be a revelation of philosophy) in propounding a theory which contradicts it; but there can be none in stating the results which follow from actual investigation: the thoughts of the mind of man may contradict revealed science (if such there be), but the works of the God of nature can hardly detect falsehood in the God of revelation. It was Copernicus, then, and not Galileo, who was the heretic, if heresy there were in the case; but the former and his immediate disciples slept in peace, while the latter was forced to sign a recantation. The story of Galileo is so well known, from the party use which has been made of it amongst us, as well as from the excellent account of Mr. Drinkwater (Bethune) in the 'Library of Useful Knowledge,' that it is unnecessary to go into details. It has been a severe lesson to the Roman Catholic Church to beware of bringing its infallibility to the practical test of a declaration in physics. We say the Roman Church, for though admitting that the seven inquisitors who signed the indictment against Galileo are not to be regarded, upon the principles of that Church, as a final authority, yet the sufferance of their decision for two centuries must be construed as the assent* of a church which is jealous above all others of what is taught or done by its ministers. The Minims Le Seur and Jacquier knew better than we can do in what state the doctrine of the earth's motion was left† by the process; their declaration at the commencement of the third book of their edition of Newton (1742) runs as follows:—"Newton in this third book assumes the hypothesis of the motion of the earth. The propositions of the author cannot be explained otherwise than by making the same hypothesis. Hence we have been obliged to put on a character not our own. (Hinc alienam coacti sumus gerere personam.) But we profess obedience to the decrees promulgated by sovereign pontiffs against the motion of the earth." We have sometimes suspected that there is a little sly satire in this last phrase of the worthy fathers. They do not represent the pope as having issued a decree against the doctrine of the earth's motion, the phrase one would have expected, but against the earth's motion: not *contra doctrinam telluris motu*, but *contra telluris motum*. At the same time, with reference to the reproaches heaped upon the whole body of Roman Catholics for this persecution of Galileo, we heartily wish that all persecutions, Catholic and Protestant, had been as honest and as mild. There is no reason to doubt the perfect good faith of the whole proceeding; and, remembering that the tribunal was one of which Galileo himself admitted the jurisdiction, and supposing the inquisitors to have believed they were doing their duty, any less amount of severity would have been a palpable respect of persons (for Galileo had powerful friends). For ourselves, we would as soon have been among the inquisitors as in the position of Galileo himself, if it be true that, on rising from his knees, after taking the most solemn oaths that he "abjured, cursed, and detested" the doctrine of the motion of the earth, he repeated aside to a friend, "*E pur si muove*" ("It does move, for all that"). We may pity, but cannot admire, either party. Not to leave unsaid any palliative on either side, we may state that the exclamation of Galileo has no very good authority, and that the inquisitors themselves were not unanimous. One of them, the Cardinal Bentivoglio, states, in his memoirs, that he did all he could to prevent the decision. It should also be noticed that the prohibitions issued at the time were mostly against works written in Italian; we cannot help suspecting that the opinion would have remained unassailed if it had been expressed only in Latin. The question just discussed was settled June 22, 1633, but this was not the beginning of the controversy. The following list of writings will save future

* The Papal power must, upon the whole, have been moderately used in matters of philosophy, if we may judge from the great stress laid on this one case of Galileo. It is the standing proof that an authority which has lasted a thousand years was all the time employed in checking the progress of thought. There are certainly one or two other instances, but those who make most of the outcry do not know them.

But the most amusing application of the case before us is that frequently made by the unknown writers who publish their own great discoveries. These generally cite the persecution of Galileo as a parallel to the neglect of themselves.

† Mr. Drinkwater states that both Copernicus and Galileo remain in the Index Expurgatorius for 1828, with '*nisi corrigatur*' to each. It is known however that the omissions and alterations with which the former author was allowed to be read were settled in 1620.

reference; they are headed by their dates:—1614, Scheiner, 'Disqu. Math. de contr. et novitat. Astron.'; 1615, Foscarini, 'Epistola Italica de mobil. terræ.'; 1615, Zuniga, 'Lett. sopra l'opin. del Copernico'; 1616, Cruger, 'Disput. de quot. telluris revol.'; 1618–1622, Kepler, 'Epit. Astron. Copern.'; 1619, Lansberg (Philip), 'Comm. in motum terræ'; also tracts of Ursinus, Campanella, and Godenius; 1619, Fienus, 'Disp. an Cœlum moveatur et terra quiescat'; 1631, Morinus, 'Famosi et antiqui problematis de telluris motu et quiete hactenus optata solutio'; 1631, Fromondus, 'Antaristarchus, sive Orbis terræ immobilis'; 1633, Galileo, 'Dial. sopra i due massimi sistemi del mondo, Tolemaico e Copernicano,' the prohibited work; 1633, Lansberg (James, son of Philip), 'Apol. comment. Phil. Lansberg in motum terræ'; 1634, Morinus, 'Resp. ad J. Lansberg Apolog.'; 1634, Rosse, 'Confut. opin. Lansbergii'; 1635, Linemann, 'Disput. math. adstruens mot. diurn. telluri vindicandum esse'; 1638, Wilkins, 'Discourse tending to prove that 'tis probable there may be another habitable world in the moon'; 1638, Bouillaud, 'Philolaus, sive diss. de vero syst. mundi'; 1640, Licetus, 'De terra, unico centro motus, disp.'; 1640 Wilkins (anonymous), 'A Discourse tending to prove that 'tis probable the earth is one of the planets'; 1642, Gassendi, 'Epistolæ duæ de motu impresso a motore translato'; tracts of Deusingius, Morinus, and others; 1643, Morinus, 'Alæ telluris fractæ, contra Gassendum'; 1643, Claramontius, 'Antiphilolaus'; 1644, Polaccus, 'Anticopernicus Catholicus'; 1645, Rheita, 'Oculus Enoch et Eliæ' (defence of the Tychonic system); 1645, Bouillaud, 'Astronomia Philolaica'; 1645, Christian, 'Disput. de trip. mundi system.'; 1645, Grandamicus, 'Nova Demonstr. immob. terræ ex virtute magnetica'; 1646, Rosse, 'The New Planet no Planet,† or the Earth no Wandering Star, except in the wandering heads of Galileans' (answer to Wilkins); 1647, Gassendi, 'Institutio Astronomica'; 1649, Gassendi, 'Apol. in Morini lib. cui tit. Alæ telluris fractæ una cum tribus Galilei Epistolis de Conciliatione Sacræ Scripturæ cum systemate telluris mobilis'; 1651, Riccioli, 'Almagestum Novum'; 1653, Dubois, 'Dialogus Theologico-astronomicus'; 1655, Herbinus, 'Examen Controv. famosæ,' &c.; 1656, anonymous, 'Demonstr. math. ineptiarum J. Dubois'; 1665, Fabri, 'Dial. phys. in quibus de motu terræ disputatur'; 1668, Riccioli, 'Argomento fisco-matematico contro il moto diurno della terra'; 1680, Bianchini, 'Dial. contro il syst. Copern.'; 1682, Megerlinus, 'Syst. Mundi Copern. demonstr.'

The controversy ceases to have any interest after the publication of the 'Principia' of Newton. Even to this day we believe there are some who deny the earth's motion, on the authority of the Scriptures, and every now and then a work appears producing mathematical reasons for that denial; these works, as fast as published, after making each two converts and a half in a country town, are heard of no more until fifty years afterwards, when they are discovered by bibliomaniacs bound up in volumes of tracts with dissertations on squaring the circle, and perpetual motion, and pamphlets predicting national bankruptcy.

We shall now recapitulate some of the arguments against the earth's motion, taking first the scriptural and afterwards the physical.

The scriptural arguments are of two kinds, Copernican and anti-Copernican; for it must be remembered that the asserters of the earth's motion, almost with one accord, admitted the Scriptures as a judge of the controversy. The following are some of the texts and arguments. We take them from Fienus, Fromond, Morin, Rosse, and Riccioli on the one side, and from their statements of their opponents' arguments, or from Wilkins, on the other.

Psalm xix. 4, 5, 6: "In them hath he set a tabernacle for the sun, which is as a bridegroom coming out of his chamber, and rejoiceth as a strong man to run a race. His going forth is from the end of the heaven, and his circuit unto the ends of it." Here it is remarked that the metaphor, where it exists, is explicit, in "as a bridegroom," "as a strong man," but that the words which apply to the sun's motion are absolute assertion.

Ecclesiastes, i. 4, &c.: "One generation passeth away, and another generation cometh; but the earth abideth for ever. The sun also ariseth, and the sun goeth down, and hasteth to his place whence he arose. The wind goeth towards the south, and turneth about unto the north." In the Vulgate, the last sentence refers to the sun: "Oritur sol et occidit, et ad locum suum revertitur, ibique renascens gyrat per meridiem, et flectitur ad aquilonem."

Joshua, x. 12: "Sun, stand thou still upon Gibeon, and thou, moon, in the valley of Ajalon. And the sun stood still, and the moon stayed. . . . So the sun stood still in the midst of heaven, and hasted not to go down about a whole day." It was contended that the earth ought to have been made to stand still, "if Joshua had been a Copernican."

2 Kings, xx. 11: "And he brought the shadow ten degrees backwards, by which it had gone down in the dial of Ahaz." Isaiah, xxxviii. 8: "So the sun returned ten degrees, by which degrees it was gone down."

Psalm xciii. 1: "The world also is stablished that it cannot be moved." Psalm civ. 5: "Who laid the foundations of the earth, that it should not be removed for ever."

* The Preceptor of Hevelius.

† Lalande gives a Latin title; we do not know whether it was published in Latin at the same time or not.

Job, ix. 6, &c.: "Which shaketh the earth out of her place, and the pillars thereof tremble; which commandeth the sun, and it riseth not, and sealeth up the stars."

Job, xxxviii. 4, &c.: "Where wast thou when I laid the foundations of the earth? . . . Whereupon are the foundations thereof fastened? or who laid the corner-stone thereof? . . . Where is the way where light dwelleth? and as for darkness, where is the place thereof?"

The Copernicans cited the preceding, Job, ix. 6, and the following, Psalm xcvi. 4, "The earth saw, and trembled;" and Psalm xcvi. 7, which in the English version, is "Let the sea roar, and the fulness thereof, the world, and they that dwell therein;" but in the Vulgate, "Moveatur mare et plenitudo ejus, orbis terrarum, et universi qui habitant in eo." The Ptolemaists replied, with reason, that these texts evidently imply a violent and unusual motion, while all the others speak of stability as the common order of things. We look upon Fromond as, next to Riccioli, the most learned and sensible of the anti-movement party, while Lansberg is certainly not the least of the Copernicans. Yet the latter, to fill up the immense void between Saturn and the fixed stars, states that it is crowded with spirits good and evil, employed in their vocations: the former meets him by the following argument. By the universal consent of theologians, hell is at the centre of the earth; the creed says that Jesus Christ "descended into hell;" and St. Paul, in Ephesians, iv. 9, that he "descended into the lower parts of the earth." The empyreal heaven, and the habitation of the blessed, must be as far as possible from hell; but the former was, by consent of theologians, at the circumference of the universe; therefore, says Fromond, the earth must be at the centre. But Morinus outdoes the rest. From the creed, he says, it appears that Jesus Christ "ascended into heaven;" and from the first chapter of Acts, that he was "taken up." It is generally thought that the hour of the ascension was noon, at which time, according to the Copernicans, the heads of persons on the earth are towards the centre of the system (the sun). Consequently it was not an ascent, but a descent, for to go towards the centre is to descend. I know, says Morin, that the Copernicans have a subterfuge and a fallacy, for they say that the ascent was an ascent with respect to the earth only; and he goes on to show what shuffling knaves they were, for so direct a perversion of plain words. It is, however, but fair to the anti-Copernican party to add that Riccioli, by far the most learned of all of them, has not thought Morinus worthy of one word of mention in his list* of writers on the subject.

Riccioli cites the following additional texts. Genesis, xv. 12: "And when the sun was going down," &c. Gen., xix. 23: "The sun was risen upon the earth." Gen., xxxii. 31: "The sun rose upon him." Judges, xix. 14: "The sun went down upon them." Matthew, v. 45: "He maketh his sun to rise on the evil and on the good;" with several others to the same purport. Also Psalm lxxv. 3: "The earth and all the inhabitants thereof are dissolved: I bear up the pillars of it." He adds all the places in which "heaven above" and "earth beneath" are mentioned.

The Copernicans, besides the very few passages which they could find alluding to a motion of the earth (and that only an unusual one), brought forward texts in which admitted errors exist; such as the Mosaic definition of the firmament, the circumference of Solomon's brazen sea (which, the diameter being ten cubits, must have been upwards of thirty-one cubits in circumference, and not thirty, as stated), and the like. To this the general answer was, that there is a great difference between stating round numbers, according to usual measurement, and absolutely asserting untruth. Riccioli however lays it down that the obvious literal sense of the Scripture is to be taken, except where it is manifestly false; that Archimedes had shown the proportion of ten to thirty to be false, but that no one had actually shown the earth to move. This was evidently convenient, but unfair; the motion of the earth was the thing in question, and could not be proved false by assuming a literal interpretation, which, it was admitted, might be rejected if the earth's motion were true.

Upon a review of the passages cited, it is clear enough that, if there be any astronomical system at all in them, it is that of an immoveable earth and a moveable sun; while if there be no astronomical system, it follows that vulgar notions are adopted in the modes of expression, which represent appearances without reference to their truth or falsehood. On one horn or other of this dilemma, all our modern Urbans must be content to abide: will they go back to Ptolemy, or forward with the advance of science? Can they show any reason why the astronomical system of the old Testament should be rejected, and those passages which appear to favour one geological theory rather than

* Since then this is a list selected by the latest writer of note, as well as the most learned, it may be worth while to give the names.

Copernicans: Copernicus, Rheticus, Maestlinus, Kepler, Rothmann (except when he followed Tycho), Gilbert, Foscarini, Zuniga, Bouillaud, Lansberg, Herigone, Gassendi, Des Cartes.

Anti-Copernicans: Aristotle, Ptolemy, Theon, Regiomontanus, Alfraganus, Cleomedes, Macrobius, D'Ailly, Buchanan, Maurolico, Clavius, Barocius, Neander, Telesius, Martinengus, Lipsius, Scheiner, Tycho, Tassonus, Claramontius, Inchofer, Fromondus, Lagalla, Tanner, Bart. Amicus, Rocco, Mersenne, Polaccus, Kircher, Spinellus, Pineda, Lorinus, Mastrius, Bellutus, Pontius, Delphinus, Elephantutius. Many of these are theologians only.

another should not only be received, but be enforced upon others by clamours of latitudinarianism, infidelity, and all those reproaches by which (and fortunately, by which only) untolerated differences of opinion are punished?

That the attempt to enforce a system of science derived from an interpretation of the Scriptures will signally fail, should be taught by the history of the past. Not even the Church of Rome will ever again dictate on a question of fact, and in Protestant countries (and Catholic too, we suspect) public opinion must and will support absolute proof against doubtful interpretation. The opponents in this matter are, some of them, men of learning, like Fromond and Riccioli; others men of conceits, like Morin.* The former seize the stronger parts of their own case, but they will find that it requires a better foundation than imposition of interpretations to bear the sort of support which the latter afford. A compact college of cardinals might more safely make the attempt than a miscellaneous party.

The declining days of what was called the Aristotelian philosophy had their span much shortened by the glaring light into which it was thrown when held up against the results of the philosophy of Galileo; and this not more by the exhibition of the Ptolemaists than of their opponents the Copernicans. The latter were taught that rational mechanics must precede simple astronomy; and it is no exaggeration to say that not an inconsiderable portion of that power over nature which we now have, can be traced in its earliest growth to the necessity of finding stronger weapons to oppose the old system than were forged in the philosophical workshops of the age we have been considering.

The physical arguments of the time consisted much in supposing inclinations, propensities, and almost feelings of privilege and place, to exist in different sorts of matter. A comet, says Fromond, is "not such an obscene ape of the planets that nature should have manufactured a sphere and a heaven for it to revolve in;" and the proper pride of a comet was the sufficient reason for one motion rather than another. The arguments for the sun's motion and the earth's stability may be condensed as follows. Aristotle and Ptolemy assert it; the Scriptures assert it (Fienus puts them second); the heavenly bodies are made for man, and the servant comes to his master, not the master to the servant; the natural motion of earthly bodies (as when falling) is in a right line; a body cannot have two natural motions, therefore the earth cannot move in a circle; if the earth moved, an arrow shot upwards could not fall on the spot from whence it was shot; the air, differing from the earth in substance, cannot be moved at the same rate, consequently, mountains, towers, &c., would produce a wind if the earth moved: a stone let fall from a height would not fall directly under the point which it leaves; an arrow shot towards the east would go much farther than one shot towards the west, the first having the air with it, the second against it; houses, and the earth itself, would be broken to pieces by so rapid a motion, which however the heavens can bear, being made of iron, according to Homer, while the earth is soft and friable; the immensity of the distance which must exist between the orbit of Saturn and the fixed stars, if the whole orbital motion of the earth produce no effect upon the latter; the excessive greatness of the fixed stars on the same supposition; &c. &c.

The Copernicans contended generally for the greater simplicity of their system, and the incredibility of the enormous velocity which the sphere of the fixed stars must have if the Ptolemaic hypothesis were true: to which it was answered, that God "doeth great things past finding out, and wonders without number;" that the earth would corrupt and putrefy without motion, whereas the heavens are incorruptible: answer—that wind, &c. give sufficient motion; that the most moveable part of man is underneath, since he walks with his feet; whence the most unworthy part of the universe (which all parties called the earth) should be moveable: answer, that the Copernicans were absurd (as in fact they were) for taking the earth out of the centre of the universe upon an argument the force of which was derived from its being in the centre (or lowest part); also, which is theoretically true, that if the earth move, the head of a man moves faster than his feet; that rest is nobler than motion, and ought therefore to belong to the sun, the nobler body: answer, that for the same reason the moon and all the planets ought to rest; that the lamp of the world ought to be in the centre: answer, that a lamp is frequently hung up from a roof to enlighten the floor; that there is a cause of motion (magnetism) in the earth: answer, that no Copernicans had examined the sun, or they might perhaps have found as good causes of motion there; that the Hebrew word for the earth has a root which signifies motion—which on the other side was contended to apply to the motion of animals upon its surface.

Such were the more common arguments of the Copernicans; others may be seen in a paper entitled 'Old Arguments against the Motion of the Earth,' in the 'Companion to the Almanac for 1836.' We do not charge every one, either of the Ptolemaists or Copernicans, with all the absurdities above noted; but we have not found one of either side

* This worthy, to a great capacity for finedrawn deduction, added the power of an astrologer, and some art in extricating himself from the scrape of an unfulfilled prophecy. When Gassendi remained alive after the time which Morin had positively fixed for his demise, the latter persisted that the non-fulfilment of the prophecy was in consequence of the warning which it gave Gassendi, whose health was declining, to try change of air.

free from such *à priori* attempts at a knowledge of the nature of things. Our countryman Bishop Wilkins has less of this sort of argument than any one except Galileo, and he deals with the scriptural objections in a very learned and able manner. He points out the absurdities into which the Fathers had fallen by a degree of literal interpretation which had become obsolete even in the days of Fromond: how, for instance—Basil made the moon greater than any of the stars, because Moses calls the sun and moon the two greater lights; Justin Martyr and several others supposed a vast body of water above the starry firmament; St. Augustine concludes the visible stars to be innumerable; many fathers assert that the heavens are not round, but stretched forth as a curtain; some that the sea not overflowing the land was not a consequence of the usual laws of matter, but a perpetual miracle; some that the sea is higher than the land, because it is called "altum," translated by us "the deep;" some that the earth is placed upon the sea; some say that the stars have understanding and speech, and, according to Origen, moral responsibility. All these things follow, either at once, or by the most universally admitted species of inference, from the literal signification of words in the sacred Scriptures. These interpretations vanished first; those who sailed round the world destroyed the greater number of them; and the abandonment of them was acquiesced in even by those who would have nailed the earth to a Hebrew word. The earth itself was next allowed to move, when Galileo had established a mechanical system which would reconcile such motion with terrestrial phenomena, as completely as that of Copernicus and Kepler with celestial. The time came when even divines might insist on this simplicity of motion in illustration of the wisdom of the architect. But the structure of the earth had not been examined; consequently when the conclusions of geological induction began to appear, the old method was ready, the texts were forthcoming, neither was interpretation wanting, nor those who would raise an outcry against the results of examination and the investigators, because the former would not agree with the interpretation, nor the latter be fettered by its imposition. The same course will be run, with the exception only that the enemies of free inquiry and honest statement are not so numerous nor so powerful as in the 17th century, so that the effect will be less, both in extent and duration. So very slight have been the scientific attainments of the opposing party on this occasion, that it becomes those who are interested in the history of the sciences to take some measures for the preservation of their writings, since it is found that the purely theological works against the motion of the earth are extremely scarce, while only those which unite science, such as it was, with theology, are now* in any degree diffused.

If we throw away all the arguments which would now be considered fantastical, we shall find the sense of both sides of the controversy contained within very narrow limits. The strength of the Copernicans lay in the simplicity with which they exhibited the celestial motions; that of their opponents, in the then unanswerable argument of the throwing up of a stone. Both parties believed that the stone of itself would not follow the motion of the earth; at least such was the opinion until the Galilean philosophy was fully received. Fromond shows his penetration when he says that the Copernican philosophy will finally be wrecked on this argument; had he admitted an alternative, and assumed either that the mechanical argument would destroy the motion of the earth, or the motion of the earth would lead to an entire change in the principles of mechanical philosophy, no one would now have disagreed with him.

We shall close this article with a mention of the actual proofs of the motion of the earth.

1. It is difficult to believe, in the present state of mechanical knowledge, that any heavenly body is at rest, and the burden of proof must lie upon those who assert rest, and not upon those who believe in motion, which a person instructed in mechanics must do, until the contrary is proved.

2. If a motion existed, a centrifugal force would arise, which would produce an effect on the oscillation of a pendulum tried in different parts of the earth. [CENTRIFUGAL FORCE; PENDULUM.] Such an effect is found to be produced corresponding to that which should be produced by the earth's rotation; nor have those who deny that rotation ever produced any explanation of the phenomenon.

3. An experiment has been tried, which it will be worth while to describe, and which Delambre says had "a sort of success." When we say that a stone let fall from the top of a high tower should fall precisely under the point from which it started, we say that which ought not to be perfectly true; the reason is as follows:—The starting point of the stone, being at a greater distance from the centre than the point directly under on the earth, describes a somewhat larger circle, and moves a little quicker. The stone therefore at the commencement of its fall has a motion from west to east, a little more rapid than the under point of the earth. The resistance of the air, though it exists with respect to the fall of the stone, does not exist with respect to the motion from west to east since the air, earth, and

* There are, it is well known, different degrees of scarceness in old works. We have met with Riccioli, Fromond, Morin, Fienus, Rosse, Wilkins, Gilbert, &c., exposed for sale in London, within these five years, and with several more than once; but we never met with any of the purely theological authors quoted by Riccioli.

stone are carried together: consequently the stone should fall a little east of the foot of the tower. This experiment was tried at Bologna by Guglielmini, who published his results in a work called 'De Motu Terræ diurno,' Bologna, 1792; it was repeated at Hamburg: the heights were respectively 241 and 235 feet (French).

In every instance the projected body fell a fraction of an inch to the east, and never to the west of the point directly under the point of projection. Had this departure been an accidental effect, it is incredible that it should always have taken place in one direction. Delambre does not state the number of experiments made; but if it were only six, and if the chances of departure east or west had been equal, it would have been 63 to 1 against the departure being always in one direction. In the last two proofs we are made to perceive the earth's rotation, by phenomena which can be explained on no other hypothesis that is worth consideration.

4. We perceive the earth's orbital motion only in the phenomenon of ABERRATION, from which one of two things must be true; either the earth moves round the sun, or light does not move in a straight line; and what is more, the light from every star, in whatever part of the heavens it may be found, changes its course with the position of the sun. The change, it is true, is minute, but it is as well established as it would be if it were visible to the naked eye; and it must be remembered that twenty seconds is not a small quantity when the eye is applied to an instrument capable of measuring one second. Were there no other phenomenon by which to test it, the orbital motion would be conclusively proved by that in question.

5. The next argument is analogy, which, though not perfectly conclusive itself, lends a great additional force to the rest. The planets all exhibit motion round the sun; this can be proved; and the only question that remains is, whether the sun move round the earth, carrying the planets round itself, or whether the earth be itself a planet moving round the sun. The planets also, in most cases, revolve round axes visibly, and there is no proof that any one does not.

6. The last argument is authority, properly used. There are many who do not know enough of the subject to decide even between Newton and the worthy Frenchman, whose name is unnecessary to mention, who thinks he proves the planets to be reflections of the sun upon the polar ice, and the southern hemisphere of stars to be a reflection of the northern upon a very curious crystal plane, but how placed we do not exactly know. With such persons authority must decide, if there be any decision at all in their minds; and it is of some importance to them to know what sort of authority they trust to. The argument from authority may be thus summed up:—1. The motions of the heavenly bodies are irregular, particularly those of the moon, which, when closely examined, exhibit irregularities, the cycles of which never were determined from observation alone. 2. At the time when the controversy about the earth's motion took place, the time of the moon's transit over the meridian, for instance, could not be predicted within several minutes. 3. By means of the labours of Newton and his successors in theory, and Flamsteed and his successors in observation, the prediction now rarely differs from the result by more than half a second of time. 4. It has been the unanimous opinion of those concerned in bringing astronomy to this state, not merely that the earth has a motion both of rotation and orbital progression, but that the proofs are such as to leave no doubt whatsoever on the subject; nor is it in history that any person who was mathematician enough to read the writings of Newton ever entertained any hesitation upon the subject.

7. For the recent experimental proofs—proofs to those who have the requisite knowledge of dynamics—of the motion of the earth, see GYROSCOPE; PENDULUM.

A short time after the article GALILEO, was first published, there appeared in a leading Roman Catholic publication, the 'Dublin Review' (July, 1838, vol. v. pp. 72-116), a controversial article upon the celebrated interference of the Inquisition. This article was much cited, and seems to have been considered by some, at least, of the English and Irish Roman Catholics as a triumphant reply to the account usually given. We shall here briefly examine the main assertions, and the question which arises out of them.

We have already expressed our opinion of the use which is made of Galileo's trial by Protestants: and we repeat that Roman Catholics have a good right to consider the manner in which this case is harped upon as a high compliment to the authority which through so many centuries possessed the power of doing as much or more on every day of every year. That the whole proceeding was disgraceful to the parties concerned is generally admitted even by Catholics; but the question, and one which has not been fairly handled by Protestants, is, how far those parties can claim to be the representatives of the church which declares itself infallible in matters of faith. The importance of Galileo's trial depends upon its connection with this question; and party zeal has mixed up with it all manner of discussion upon the character of the proceeding itself, and the motives of those who originated it. Englishmen would do well to remember, with regard to the latter points, their own Star-Chamber, the astronomy* of the Act of Uniformity,

* The poor nonconformists (see Calamy's 'Life of Baxter') pleaded in vain that they were required "unfeignedly to assent and consent" to declarations which distinctly implied that it was full moon at times when any one could see

and the decision of the University of Oxford * that no woman has a right to defend herself against the king.

Even in Italy the defence of the Inquisition has been long and openly given up by many. Witness the expressive silence of the account of Galileo, in the 'Elogi degli Uomini illustri Toscani,' Lucca, 1772, taken from a contemporary Milan periodical; the declaration of Frisi (Milan, 1775) that "the imagination is horrified, and the virtuous and feeling mind shudders," at the language applied to Galileo in the sentence passed upon him; and that of Fabbroni (Pisa, 1784), that "it is better to be silent upon the details than by recalling them to increase the horror which every virtuous mind ought to feel against the injustice of that time." And the article in the 'Dublin Review' styles the Inquisition "superlatively cruel in Spain, more mild and sparing of human life in Rome"—only more mild than superlatively cruel.

That the Roman Church decided against the earth's motion has been generally affirmed by Protestants, and denied by Catholics, we believe, with justice. But that the church which claims infallibility in essential matters suffered two local tribunals, the office of which was the suppression of heresy, to pronounce, and, as it turns out, to pronounce wrongly, upon a question of astronomical fact, is all but universally admitted. Nevertheless, even this is denied altogether by the author of the article before us, whose account of the matter is as follows—That Galileo, in 1615, not content with supporting the Copernican doctrine as a truth, which it was open to him to do, persisted in invading what himself admitted to be the prerogative of the church, by declaring that the sacred Scriptures could be interpreted against Ptolemy and for Copernicus; and this, in spite of many friendly warnings, that he must confine himself to "demonstrating his system," and writing "as a mathematician, and by way of hypothesis." That when the first attempt was made upon him in 1615 (which was rejected by the Inquisition for informality), as much licence as the above was distinctly mentioned as given to all. That the prohibition of 1616, to teach or write in favour of the Copernican doctrine, was a prohibition to Galileo only, not to others, and was brought about partly by Galileo's persisting in forcing the theological question upon the court, and partly by the imprudence of his advocate, Cardinal Orsini, in pressing the subject upon the pope. That before this prohibition was given, on the occasion of Galileo's first personal appearance, the qualifiers of the Inquisition, whose office it is to put the propositions bearing on the points at issue before the court, drew up the two famous theses, in which the doctrine of the earth's motion was called false and heretical. That when Galileo, in 1632, brought on the proceeding of 1633, not only by a breach of the prohibition, but by a sarcastic reference to it, and a caricature of the arguments of his friend and benefactor, the reigning pope, these theses were merely cited in the preamble of the sentence, and are not there to be taken as anything but recapitulation. That the word heretical, in the proceedings of the Inquisition, is the *stylus curiæ*, and that even offences against morals or the public peace, apart from all doctrine, must be styled heretical, before that court can assume jurisdiction.

In the above are the following assertions. 1, That any one (except Galileo, restrained for his own misconduct) was at liberty to teach the earth's motion as true, provided he confined himself to philosophy, and let theology alone. 2, That the Inquisition pronounced no opinion upon the truth of the doctrine. 3, That it pronounced no opinion upon the orthodoxy of the same. We deny each of these positions, upon the clearest reasons, which we shall bring forward. But we do not deny that much has been stated which, when closely examined (for articles in reviews do not deal in references), would probably establish the fact that the prohibition of 1616 was mainly due to the injudicious ardour with which Galileo pressed the theological question. Nor do we deny that the conduct of the philosopher was weak and ungrateful in putting into the mouth of the wrongheaded personage of his dialogue the arguments urged to him in personal conference by his benefactor Urban, with a hint that they came from a high quarter. All parties admit that it was the irritation of the pope at this conduct which led to the final proceeding.

As to the first of the preceding assertions. There were, at the time in question, three distinct modes of maintaining a theory. First, as a

that it was little more than half moon. And to make this more remarkable, it should be remembered, that in the year following it was proposed to insert into the act for relief of those who had not subscribed on account of sickness, a clause declaring the assent and consent to be nothing more than a declaration of obedience. This clause passed the Lords, but was rejected by the Commons, and the bill passed without it.

* It was in 1622, between the two proceedings against Galileo, that the Convocation at Oxford promulgated this doctrine. (Wood, 'Historia,' &c., pp. 326-328.) William Knight, with a meaning perhaps both seditious and offensive, had publicly maintained that if the sovereign were to attack a subject, *tanquam latro aut stuprator*, and if no other help were nigh, the subject might defend himself or herself as against any other assailant. The university, not content with committing Knight to prison, declared the proposition false, dangerous, and impious; and enacted that all candidates for degrees should subscribe this censure, and make oath that they would neither hold, teach, nor defend this opinion. The false physics of the Inquisition seems to have the evidence of the senses in its favour; the false morals of the Oxford convocation has always found its denial in the heart and conscience of every honest man and of every honest woman.

mathematical hypothesis, assuming it not as true, but as sufficient to explain phenomena, and leaving its truth or falsehood aside, or even implying the latter. Secondly, as a truth, but without any reference to the Scriptures: maintaining it by arguments, and implying that if the Scriptures really assert the contrary, there must be something wrong in those arguments, but that if the latter really amount to demonstration, then the interpretation of the Scriptures, which makes them assert the contrary, must be wrong. Thirdly, as an absolute truth, confirmed by reason and Scripture both. In the article we are examining, the first and second of these modes are confounded: and it is thought that when Galileo was warned off the third mode, and told to write "as a mathematician and by way of hypothesis," and to confine himself to "demonstration," he was left with permission to use the second mode. This is not correct, but the mistake is a natural one. We have already seen [DEMONSTRATION] that demonstration, as applied to physical hypothesis, meant only explanation: and that it could be said that a false hypothesis might give true demonstration; that is, might be shown to be capable of accounting for phenomena. To learn how matters stood in the present case, we must look to the words of the authorities. Of these there were two, the Inquisition, which took cognisance of the acts of heretics, and the Congregation of the Index, which examined and censured their books. In one and the same year (1616) the former silenced Galileo, the latter condemned the great work of Copernicus, and the writings of his followers. The decree which condemns them calls the doctrine of the earth's motion "false and altogether contrary to Scripture." And this decree prohibits not only the work of Foscarini, which endeavours to show that the doctrine is not contrary to Scripture, but also that of Copernicus, which does not touch the question of theology. This is plain enough, but we can make it still plainer. Four years after (1620), the same Cardinals of the Index, finding that the work of Copernicus could by slight alterations be made to speak the language of hypothesis, published the corrections under which they would allow it to be read. We put a few sentences of the work side by side with the alterations dictated by authority:—

Copernicus.

This question (of the motion of the earth) is not yet settled, and is not to be despised by any means.

Since then there is *nothing* to hinder the motion of the earth.

On the triple motion of the earth (heading of a chapter).

These three stars (the earth being one).

This surely will settle, in reasonable minds of all persuasions, the question how much is permitted to a person speaking as a mathematician, and by way of hypothesis. If Copernicus say the earth is a star [a word implying motion], the cardinals strike it out: if that it may be so, they alter it into a professed assumption for purposes of calculation. How indeed could they allow *nihil prohibet* on an opinion described by themselves as *Divina Scriptura omnino adversantem*? For the documents cited see Riccioli, 'Almag. Nov.' lib. ix. sect. iv.

Next, as to the assertion that the Inquisition pronounced no opinion on the truth of the doctrine. The two propositions, affirming both its falsehood and heresy, were drawn up, it is said, by the qualifiers or qualifiers, inferior officers of the court, and not the court itself. This is a strange argument, and to make it relevant to any point it must be shown that the declaratory power of the Inquisition was lodged in its inferior officers, and not in its judges. If the tribunal were so constituted, it matters nothing to the point in question; for the qualifiers did declare against the doctrine, that is, the court did pronounce a decision in its usual form and manner, and we assert nothing more. All that was done in any other case was done in this one. But in point of fact, it will be found that the qualifiers are only the assistants of the judges; and the voluntary adoption of their conclusions by the cardinals makes those cardinals themselves the responsible parties. But further: it is not true that the final sentence of 1633 did no more than state the theses of the qualifiers as recapitulation of the proceedings of 1616. The defence before us asserts that the Inquisitors "did not at all trouble themselves with considering the truth or falsehood, the innocence or poison, of the opinion asserted." To this let the sentence itself reply:—"And that this pernicious doctrine might be altogether removed, and might not further creep in, to the great injury of Catholic truth, a decree emanated from the Sacred Congregation of the Index, by which the books which treat of this doctrine were prohibited, and the doctrine itself was declared false, and altogether contrary to Scripture. But since a book has appeared at Florence in the past year (1632), of which the inscription shows that you [Galileo] were its author, the title being 'Dialogo,' &c., and whereas the sacred Congregation has come to know that since the printing of that work the false

Correction required.

It matters nothing whether the earth be taken as the centre [remember that the word centre in those days implied immovability] or not, so far as solving the phenomena of celestial motions is concerned.

Since then *we* assume the motion of the earth.

On the *hypothesis* of the triple motion of the earth.

Omit these words, because the earth is not a star, as Copernicus makes it to be.

opinion of the motion of the earth has increased more and more from day to day, the said book was diligently considered," &c. And in the recantation Galileo is made to say that the opinion of the earth's motion is false and heretical, and that he abjures and detests that error and heresy. It thus appears that there are four parties who declare the doctrine false and heretical—the qualifiers, the Inquisitors, the Congregation of the Index, and (perforce) Galileo himself.

Next, as to the question whether the Inquisition declared the doctrine heretical. That, so far as its authority extended, and in its own usual sense and meaning of the word, it did do so, is clear enough from what precedes. But, as may be supposed, a general word which belongs to an extensive system of law has many uses. The argument about the *stylus curie* seems to us unanswerable. In our Court of Queen's Bench, peaceful persons were adjudged to have done many things by force and arms, because the court, originally instituted for matters connected with the Queen's peace, had no other way of widening its jurisdiction for the relief of the subject except by interpreting one class of injuries after another as acts of violence. The Inquisition, instituted for the suppression of heresy, and having no choice but to determine all causes sent before it by the Pope (as was that of Galileo), was as much compelled by its forms to consider every point with nominal reference to heresy and orthodoxy, as the Court of Queen's Bench to decide actions for breach of contract on a supposition of money detained by force. Whether the maxim of our law—in *fictione juris semper subsistit æquitas*—can be applied to the Office called Holy; whether the high authority which Roman Catholics reckon to be infallible when it *does* pronounce a decision was not culpably negligent in withholding its power from the scene of action, and in allowing an inferior tribunal to assume the function of interpretation which it asserts to belong peculiarly to itself—are questions on which Roman Catholics themselves are likely enough to be divided in opinion. But however this may be, to require them to admit that their church has decided against the motion of the earth, as a matter of faith, and in its asserted infallible character, is to ask them to yield more than the opponents of the disputed doctrine ever thought they could claim as having been done for them. On this point we can cite a most unwilling contemporary witness, Fromond of Louvain, whose 'Antaristarchus,' written against the motion of the earth, was published at Antwerp in 1631. Fromond was a very zealous Roman Catholic, an ardent opponent of the Copernican doctrine, and a firm believer in the fact of the sacred writers having intended to declare the stability of the earth. One of his chapters is thus headed, "Is the Copernican opinion now to be held heretical?" This of itself is something, for it is to be remembered that the work had passed through the hands of the united censure of Philip IV. of Spain and the ecclesiastical authorities. What would these examiners have said to a work on the Nicene Council with a chapter headed "Are the followers of Arius to be considered as heretics?" But to proceed:—Fromond, who wants to get all the condemnation that he can for his opponents, begins by citing Roman Catholics who have expressed opinions on the subject: and it is remarkable how mild the censure is, even of those who wrote after the decree of the cardinals. Tanner says the opinion is "condemned, and cannot any longer be safely held;" Mersenne, that "any one may justly think it rash,* particularly after the manner in which the cardinals have expressed themselves." The author goes on to state, with a slight, but very slight, tone of reproach, that there are men, both learned and Catholic, in Italy, France, Germany, and Belgium, who care little for the opinion of the cardinals, and who say that the power of these dignitaries is not supreme and pontifical, and that until this last-named power is exerted, they are safe and not within the limits of heresy. But Fromond doubts whether they are "safe enough." He points out that the books which are in the Index are condemned (according to the bull of Sextus V., which modelled both the Index and the Inquisition into the form which they had when Galileo was silenced) by the authority of the pope, expressly delegated for that purpose; and he then feels justified in drawing the following inference. "If," says he, "the general opinion of the Catholics of our time be correct, namely, that the pope speaking *à cathedra* cannot err, though not supported by a general council, then it is all up with Copernicus, and his paradox (to use a gentle word) appears rash, and next thing to heresy, ay, even more." Having thus, as it were, made his utmost point, and still not got quite so far as heresy infallibly pronounced, he checks himself thus: "This is what a severe judge might think. But when I consider how circumspect and free from haste pontiffs generally are in their decrees on matters of faith *à cathedra*, and also their practice of making those decrees in their own names and not in those of others, and since Sextus V., in the diploma which established the fifteen congregations of cardinals expressly says, 'Of those decrees which relate to the dogmas of the faith, we reserve the interpretation to ourselves'—it seems necessary to mitigate the censure

* This word rash, *temerarius*, is of great force. It had a technical meaning, and was constantly used at the time of which we write, as for aught we know it may be now, as an epithet distinctive of an offence minor to heresy. Accordingly when a priest styles the opinion *rash*, it is to be inferred that he would refuse to say it was *heretical*: just as hearing a lawyer call an offence manslaughter, we should suppose him to deny that it amounted to murder. So that, when Mersenne qualifies as only *temerarium* that which the court of which he is speaking had pronounced *falsum et formaliter hæreticum*, he limits the power of that court in the same manner as Fromond did, though more briefly.

a little, and right to suppose that the authority of the Congregation of the Index is not equal, but inferior, to that of the pope." He ends by saying that though the Copernican has (unless the pope should otherwise decide) one foot inside the door of heresy, yet he would not dare to pronounce him an open heretic, without something more express from the head of the church. The bull of Sextus V., as we see, contains an express limitation of the power of the several congregations; and the language and arguments of Fromond (to whom we might join other writers, but not of so satisfactory a character, as being themselves Copernicans) prove that this renunciation of the charge of heresy, this declaration that the asserted infallible power never showed itself, is no subterfuge of modern Romanists, but was the argument of the time when Galileo was under the ban; was held, among others, by a distinguished opponent of the Copernican doctrine, the very last person who was likely to have had any bias towards such reasoning; and was allowed to pass a strict censorship of the press.

In 1651 the theologian Riccioli, the most learned of astronomers, and the strongest of the anti-Copernicans, writes as follows:—"The sacred congregation of cardinals, taken apart from the supreme pontiff, does not make propositions to be of faith, even though it should actually define them to be of faith, or the contrary ones heretical. Wherefore, since no definition upon this matter has as yet issued from the supreme pontiff, nor from any council directed and approved by him, it is not yet of faith that the sun moves and the earth stands still, by force of the decree of the congregation; but at most, and alone, by the force of the sacred Scripture, to those to whom it is morally evident that God has revealed it. Nevertheless, Catholics are bound, in prudence and obedience, at least so far as not to teach the contrary. But of this subtlety* of theology I have treated in my treatise 'De Fide.'"

But not only do Roman Catholic writers thus express themselves, but contemporary Protestants, the most staunch opponents of Rome, accept the interpretation. Thus Bishop Wilkins, a decided Puritan, writing in 1640, after stating that some individuals, as Serrarius, expressly condemn the Copernican doctrine as a heresy, proceeds as follows: "And since him, it hath bin called in [question?] by two Sessions of the Cardinals as being an opinion both absurd and dangerous. And therefore likewise doe they punish it, by casting the Defenders of it into the Pope's truest Purgatorie, the Inquisition: by yet neither these Councils, nor any (that I know of) since them, have proceeded to such a peremptorie censure of it, as to conclude it a heresie; fearing, perhaps, lest a more exact examination, and the discoverie of future times, finding it to bee an undeniable Truth, it might redound to the prejudice of their church, and its infallibilitie."

It is moreover to be remembered that the Inquisition, and even the Congregation of the Index, was a local authority, incompetent to legislate for the faith of all Roman Christians. There was nothing in what was done by the Italian to hinder the Spanish Inquisitors from declaring in favour of Copernicus, if such had been their pleasure: and, in fact, we have searched the Spanish Index of 1667 in vain for the name of Copernicus, though some of his followers are in the list.

Lastly, if we remember the controversy which has always existed in the Roman world as to the character of decrees emanating from the Roman See alone, without a general council, we shall see that it would have been very unlikely that a pope should have raised this question in France, Spain, and Germany, upon a matter which might any day be settled against him by absolute demonstration. Tiraboschi looks upon it as a special Providence that the Church was not allowed to commit itself; and we apprehend that most Roman Catholics will be of his opinion. But they must admit, as they have had to do in many other cases, that their earthly head used his power in a most unworthy manner, and found agents who were the subservient creatures of his irritated feelings. Protestants, on the other hand, should beware how they weaken the general argument against the infallibility of the Roman church, by practically owning that it cannot be successfully attacked except by denying to those who maintain it the right to be the interpreters of the sense in which they use their own words.

Though we differ entirely from the article in the 'Dublin Review,' the substance of which we have quoted, yet it is right to say that we find in it a large quantity of collateral information, put together in a manner which strikingly exhibits the under current of favour which was setting towards the doctrines of Copernicus, when its imprudent advocates began to mix theological with their physical arguments. Had we intended this comment to be a biographical one, we should have had to make use of its details; and we should be very glad to see the numerous interesting citations which it contains worked into truer history, supported by fuller reference, and dignified by milder language towards opponents.

MOTTO, an Italian term, shortened by some of our old writers to *mot.* It means a word or sentence added to a device; and is commonly used, when put upon a scroll, as an external ornament of coat-armour. The use of mottoes for this purpose is ancient, and as appended to a coat of arms they are frequently hereditary in families. In strictness,

* Delambre says that Riccioli confesses his argument to be a *subtlety*: but Delambre only knew the word as used in his own vernacular. A subtlety, before the word became one of reproach, meant a distinction requiring explanation, and was applied by Copernicans themselves to their own doctrine.

the motto should bear allusion to something in the achievement, but in modern times the taking of it rests entirely with the fancy of the bearer, and it may be changed at pleasure. A sentence or quotation prefixed to anything written is also termed a motto.

MOULDINGS (in Architecture), any assemblage of narrow surfaces projecting from the face of a wall or other surface and also advancing one beyond the other. They are bounded by straight lines, either horizontal or vertical, according to their situation, but the surfaces themselves are *plane* or *curved*, and if the latter, concave or convex, or else compounded of both forms. Sometimes indeed, instead of projecting, mouldings are *sunk*, as is the case when they form a border within a sunk panel, for though they project with respect to the surface of the latter, they recede within the general face of the wall. The mouldings within the panels of doors are of this description. Mouldings are employed as borders to doors, windows, and other apertures, as arches, in which latter case they are termed *archivolt mouldings*; while those forming the imposts from which the arch springs are called *impost mouldings*. The bases of columns likewise consist of mouldings. They are also employed to mark the horizontal divisions of a wall, both internally and externally, and every member to which they are applied is said to be *moulded*. As their edges are straight lines, their contour can be shown in drawings only by their shadowing, and by the outline which they produce at their extremities, as in the case of a cornice. But as this is insufficient, except to afford a general idea, in working drawings and those of detail mouldings are shown on a larger scale, and by means of a section through them, by which their *profile* is accurately defined; and upon a good profile, that is, one where the mouldings are well proportioned to each other, and so combined as mutually to relieve each other, and to produce both an agreeable variety of surfaces and of light and shade, much of the beauty and finish of a building depends.

Mouldings are distinguished by different names, according to their *profiles*, their sizes, or their situations. Thus the *fillet*, *tænia*, *band*, are all plane or flat mouldings, the only difference being that the first-mentioned is narrower than the others, and frequently is not so properly a distinct moulding as a space left between other surfaces, or else a rim to a larger moulding, as to a cymatium terminating a cornice, &c.; while *tænia* is the name given to the broad fillet separating the architrave from the frieze in the Grecian Doric entablature, and *band* is applied to any still broader plane surface—thus if instead of dentils, in an Ionic or Corinthian cornice, a projecting plane surface be left where they would occur, it is called an *uncut dentil band*. The *corona* (one of the principal members in every cornice) is also a mere plain band, except that it is occasionally enriched in Roman architecture. Again, lesser convex mouldings are termed *beads*, but the longer mouldings of the same kind in the bases of columns are termed *tori* or *torusses*. The *cyma recta*, or *cymatium*, is a compound moulding, concave above and convex below; while the *cyma reversa*, or, as it is technically termed by workmen, the ogive or ogee moulding, is convex below and concave above. The *cavetto* is a mere hollow or sweep, intervening between and serving to connect two mouldings, one of which projects beyond the other. The *scotia*, or hollow between the upper and lower torus of the base of a column, is a moulding of this kind upon a large scale, and has therefore a distinct name assigned to it, which also points out its situation. The *ovolo* is a simple convex moulding, so called because it is generally carved into *ova*, or ornaments in the shape of eggs, within hollows. The ovolo of the Doric capital (which is always uncut) is distinguished by the name of *echinus*. All the other mouldings may be carved or enriched, except the *cavetto* and *fillet*; the pattern being accommodated to the surface of the moulding. The *cyma recta*, or *talon*, as it is sometimes called, is cut with a peculiar kind of tongued or arrow-headed ornament.

These mouldings are common to both Grecian and Roman architecture, but besides being more profusely applied in the latter style they have this marked difference, that in Roman architecture the curved mouldings, whether simple or compound, are described by quarter circles, whereas in Greek they describe other curves obtained from conic sections, and are therefore not only more elegant in their contour, but susceptible of far greater variety. Some of them are also occasionally *undercut*, that is, hollowed out below and behind, whereby, while a greater depth of shadow is obtained, a greater sharpness of lines and lightness of form are produced. Of this kind is what is now distinguished by the name of the *bird's-beak moulding*, because its section produces an outline very much resembling that of the hooked upper and lower mandible in the beaks of some birds.

In Gothic mouldings, undercutting is very common, and hollows or recesses more or less deep are frequently numerous in the profiles of mouldings in that style. The mouldings are also for the most part produced by *splayed* or *bevelled* surfaces, that is, slanting or turned obliquely from the outer face or general plane where they occur. In that style the mouldings are so numerous, and the profiles produced by them so complex, as to render it impossible to describe or characterise them further. They are however of the utmost importance, both as adding greatly to the effect of buildings, and as assisting in the discrimination of the several styles or periods to which the buildings belong, and therefore require to be well studied and perfectly understood, for which purpose such works of detail as Pugin's 'Gothic Specimens,' and 'Gothic Examples;' Paley's 'Manual of Gothic Mould-

ings, &c., may be recommended: the unprofessional reader will probably find sufficient information on the subject in 'Paley's Manual of Gothic Architecture,' Bloxam's 'Principles of Gothic Architecture,' or any of the other accepted guides to the study of Gothic architecture; see also the articles GOTHIC ARCHITECTURE, and NORMAN ARCHITECTURE. One circumstance however which ought to be mentioned is that the mouldings all recede within the face of the wall (like those of panels), except labels, hood-mouldings, and others, that come under the general denomination of *weather mouldings*, because made to project instead of recede, and therefore more exposed to rain and weather.

In regard to Grecian mouldings, it remains to be observed that many of those which are uncarved, and therefore supposed to have been quite plain, were painted with some ornamental pattern, and that not unfrequently in the most brilliant colours. But this mode of decoration is treated more at length in the article POLYCHROMY.

MOUNTAIN BLUE. [COLOURING MATTERS.]

MOUNTAINS. [OROGRAPHY.]

MOVEMENT, in Music, a detached and independent portion of a composition. Symphonies, concertos, quartets, sonatas, vocal pieces of various kinds, &c., are divided into portions commonly differing from each other in time as well as in key, and every such portion is called a movement. Most symphonies are divided into an introductory slow movement, then a quick movement, an andante, a minuet, a trio, and another quick movement. The Pastoral Symphony of Beethoven, however, consists of five movements, namely, 1, a Country Scene; 2, The Rivulet; 3, The Village Dance; 4, The Storm; 5, as a *finale*, The Shepherd's Song.

MOVING FORCE may be defined as force considered with reference to the momentum it produces, in like manner as accelerating force means force considered as the cause of acceleration.

Apply continued pressure to a weight of 10 lbs., such as will in one second produce a velocity of 80 feet per second; apply another pressure to a weight of 7 lbs., such as will also in one second produce a velocity of 50 feet per second: the momenta produced in one second are then as 10×80 to 7×50 , or as 800 to 350, and the moving forces are said to be in this proportion. The following equation is made the measure:—

$$\text{Moving force} = \text{mass} \times \text{accelerating force};$$

but this is on the supposition that a unit of acceleration produced in a unit of mass shall require the amount of pressure which is taken as the unit of moving force. [MASS; MOMENTUM.]

The connection of momentum and acceleration are developed in VELOCITY and VIRTUAL VELOCITIES. It is necessary to remind the young student in mechanics that accelerating force is a mathematical abstraction, the conditions of all problems which actually occur introducing as data not accelerating forces, but moving forces. (See third law of motion, in MOTION, LAWS OF.) Owing, however, to the problems which usually come earliest in mechanical treatises containing only accelerating forces among their data, or given laws of acceleration without reference to the masses in which acceleration is produced, or the pressures which produce them, the learner is not sufficiently reminded of this.

MOVING POWERS. The means employed to give motion to machinery, independently of the cases in which the force of gravity is applied directly, as in turning the cylinder of a clock, are the strength of men and animals, the pressure of the atmosphere, the expansive force of steam, and the action of wind or water. It is even possible that the recently proposed actions of the galvanic fluid and of fired gunpowder will in time be numbered among motive forces for impelling carriages, vessels, or machines. The first and second of the powers above named are treated under ANIMAL STRENGTH and ATMOSPHERIC RAILWAY, and the force of steam under STEAM-ENGINE.

The intensity of a moving power is always estimated by the amount of the resistance which is overcome and the space through which the equivalent of that resistance is conveyed, or raised vertically, in a given time. Thus, in the article on ANIMAL STRENGTH, it has been shown that a man, a horse, &c., can convey a certain weight, expressed in pounds, through a certain number of miles during a working day; and the continued product of the weight, the distance, and the time has been made to denote the intensity of the power, one pound being the unit of weight, one mile that of distance, and one hour that of time: in estimating, however, the power of an engine or machine, it is usual to consider one foot as the unit of distance and one minute as the unit of time, one pound being the unit of weight; the action of the power is, moreover, supposed to be continued during all the time that the machine is at work.

Originally the larger kind of engines, except such as were impelled by wind or water, were moved by the power of horses; and when other agents were employed, the gross effect of the engine was estimated by the number of horses to whose action it was equivalent; but the intensity of horse-power is very variable, and some inconvenience was at first, on that account, experienced in estimating the relative values of engines. In order to establish, conventionally, this dynamical unit, Messrs. Boulton and Watt ascertained from trials, purposely made, that a strong horse can draw 125 lbs. at the rate of 3 miles per hour during 8 hours: therefore the measure of the power may be expressed by

3000 lbs. ($= 125 \times 3 \times 8$) drawn or raised 1 mile in 8 hours; or, multiplying by 5280, the measure is 15,840,000 lbs. raised 1 foot in an equal time. This product, being divided by the number of minutes in 8 hours, gives 33,000 lbs. for the weight carried or raised 1 foot per minute continually; and the last number is now universally adopted as a measure of the intensity of the power of a horse. Therefore, when an engine is said to have the power of any number n of horses, it is understood that it is capable of raising $33,000 n$ pounds' weight to the height of 1 foot in every minute during the continuance of its action. [HORSE-POWER.]

The method of estimating power by a weight carried or raised through a certain space in a certain time is capable of being applied to all engines: thus, in drawing a carriage along a road, the resistance of the carriage must be equivalent to some weight; and the reaction of the water against the paddles of a steam-vessel may always be represented by a certain weight which, if it were lifted by the wheel, would oppose a resistance equal to that of the water. For the useful force of steam-engines in terms of the volume of water evaporated, the pressure of the steam, the length of the stroke, &c., see STEAM-ENGINE.

Wind and water are employed as prime movers by means of the momentum arising from their velocity; and the latter, occasionally, by the pressure arising from its weight. The manner in which the force of wind is made to act in giving motion to vessels on the surface of water will be fully explained under SAIL, and in producing the revolutions of windmill sails under WIND-SAIL; it is intended, therefore, in this place, merely to explain the method of forming an equation of equilibrium for the power of an oar in giving motion to a vessel, and to show the force of water on the paddles or float-boards of wheels which are turned by that element.

Let MN represent one side of a vessel, AB the position of the oar when its blade enters the water, and E the fulcrum or side of the row-

lock against which it presses; then, since the vessel will move forward during the time that a stroke of the oar is being made, let F be the position of the fulcrum and CD the position of the oar at the end of the stroke: if the vessel had remained at rest, the oar, at the end of the stroke, would have had the position cd , which may be considered as parallel to CD .

Now, B being the centre of percussion on the blade of the oar, the actual motion of B (supposed to be parallel to the keel of the vessel) may be represented by Bd while the movement of the vessel is EF ($= Dd$); and therefore BD represents the relative movement of B . The lines BD and Dd being proportional to the velocities of the oar and vessel, which velocities we may represent by v and v' ; $v - v'$ will express the relative velocity of the oar, and the effective power of the latter will vary with $(v - v')^2$. Let a , in square feet, be the area of the blade of an oar, and let the pressure of water against a square foot of surface be $1\frac{1}{2}$ lb. when the velocity is 1 foot per second; then $\frac{3}{2} a (v - v')^2$ will denote the force of the oar.

If, for simplicity, the prow of the vessel be supposed to have the form of a wedge with plane faces meeting in a vertical line, or cut-water, on putting a' for the area of the whole prow and θ for the inclination of each face to a vertical plane passing through the keel, we shall have

$$\frac{3}{2} a' \sin^3 \theta \cdot v^2$$

for the resistance of the water against the prow. Therefore, n being the number of oars all of which are supposed to act with equal forces; we have, when the vessel has acquired a terminal velocity,

$$n a (v - v')^2 = a' v'^2 \sin^3 \theta,$$

from which v' may be found. The velocity of a vessel moved by oars is, however, found to increase in a less ratio than the number of oars.

The power of the oar in rowing appears to be diminished by the reaction of the feet of the rowers in pressing against the foot-boards; this has a tendency to force the vessel backwards, but it is compensated by the greater velocity which the centre of percussion in the oar thereby acquires. Some force, however, is lost in overcoming the inertia of the oar, and in bringing it forward against the air; this last force is considerable when the vessel is rowed against a high wind, though it is to a certain degree diminished by the practice of feathering the oars.

The above equation might be used to determine the velocity of a vessel impelled by steam, in which paddle-wheels are employed, if it were possible to determine, nearly, the value of na , or the number of square feet of paddle which, on both sides of the vessel, are at every

moment acting efficiently against the water: the value of v would be, of course, determined by the number of revolutions which the wheel makes in a given time; and it should be expressed by the number of feet per second which the centre of percussion in the paddle moves through in turning about the axle.

The momentum of water flowing horizontally against a plane, such as a float-board of an undershot wheel, depends on its velocity, on the area of the surface with which it comes in contact, and on the obliquity of that surface to the direction of its motion; and in estimating the effect of water on such a wheel, it is necessary to determine from the dimensions of the channel and the velocity of the water in it the weight of water which descends vertically through a certain height, as one foot, in a given time. The product of this weight multiplied by the height actually descended, being compared with the product of the number of pounds which the wheel can raise to a certain height in the same time multiplied by that height, expresses the ratio of the power to the effect. From many experiments, Mr. Smeaton concluded that, when the quantity of water expended is the same, the useful result varies nearly with the head of water, or with the square of its velocity.

The power of an overshot wheel is estimated by the product of the weight of water expended in a given time multiplied by the whole weight of its descent—that is, by the sum of the diameter of the wheel and the height of water in the reservoir above the top of the wheel. The useful effect of an overshot wheel is said to be nearly double that of one which is undershot.

In determining the power of water on breast-wheels, it is customary to consider such a wheel as one compounded of an undershot and of an overshot wheel; and its effect is conceived to be equivalent to that of an undershot wheel whose head of water is equal to the difference in height between the surface of the water in the reservoir and the point at which the water impinges on the wheel, together with the effect of an overshot wheel whose height is equal to the difference between the point of impact and the level of the tail-water.

MOXA, a word of uncertain origin, signifying any substance whose gradual combustion on or near the skin is used for the relief or cure of disease. This method was early practised in the East, particularly by the Chinese and Japanese, from whom it was copied by the Portuguese; but having fallen into disuse, it was revived by the French surgeons during the Egyptian campaign. The substance employed by the Chinese is formed of the downy covering of the leaves of the *Artemisia Moxa* (De Candolle): but the down of many other plants, or the pith, may be used. The stalk containing the pith of the common sunflower (*Helianthus annuus*) is a very convenient means, when the prepared moxas cannot be procured. Those used in Britain are all imported from France, and generally consist either of a pyramidal or cylindrical roll of linen, which is mostly steeped in a solution of nitrate or chlorate of potass. The size of this is generally about eight lines high, and from four to five broad. It is ignited at the one end, and the combustion gradually extends to the other. This differs from the actual cautery by means of a red-hot iron, inasmuch as the latter produces immediately its maximum of effect, which progressively diminishes, while in the case of the moxa the heat gradually increases, and the greatest effect is produced towards the end of the operation. It is also different from a blister, both in its mode of action and in the stage of a disease in which it may be most advantageously applied. The general principles which should regulate the use of blisters having been already explained [BLISTER], as well as those connected with the actual cautery [ESCHAROTICS], the following observations refer to the distinctive characteristics of the Moxa. We may remark that the pain is not so great as might be expected, indeed less than often attends blisters, and that it is often borne by females and children, or at least boys, with the greatest fortitude.

Besides the secondary effects of the local application, which, being of a counter-irritative kind, are common to blisters and moxa, in the case of the latter there is the additional influence of a certain amount of caloric. "Caloric, applied under certain circumstances and with appropriate restrictions, stimulates in a powerful manner the capillary vessels, causing them to contract their diameters, and to circulate their blood with greater velocity; and, either by this action on the capillaries, or by a direct one on the lymphatics of the part, it has also the power of exciting the function of the absorbents in a remarkable manner. The direct effects of moxa are seldom, if ever, confined to the skin; and if the moxa be applied through the medium of a needle, the caloric may be made to propagate its influence to any depth. The beneficial influence of moxa, in relieving or curing disease, apparently depends on its tonic action over absorption and capillary circulation. Hence it should be employed in those cases only in which there exists a state of debility of the capillaries and a consequent retardation of their circulation, and a diminution of absorption; and invariably avoided wherever there is increased action or active inflammation."

To hold the moxa over the part affected, an instrument has been invented, but a portion of silver-wire formed into a loop, surrounding the cylinder near the base, is sufficient. The moxa may be applied in various ways. "It may be used so as not to cause any injury; in a greater degree, so as to produce vesication; and in a still greater degree, an eschar, which may be either deep or superficial; or it may be

employed with the acupuncture needle." In the first form, it is burnt near, but not in contact with, the part affected, and is often of great service in healing indolent ulcers; it generally requires to be applied once a day. It is even used in some chronic inflammations of the eye with very good effect. In the second form it is also to be held near the skin, and continued till a blister results. In tic douloureux of very superficial nerves this is sometimes beneficial. The third mode is the most common, and for this the part to which the moxa is intended to be applied is marked out, and the moxa being surrounded with a piece of card-paper, which has been moistened with a solution of common salt, to protect the adjacent skin, the moxa is ignited at one end, and the combustion increased, if necessary, by means of a blow-pipe. For the cure of obstinate sciatica and deep-seated diseases of the joints a frequent repetition of the moxa may be required, but it seldom fails to give relief. "When the moxa and acupuncture needle are used together, a moxa of a proper size is to be perforated by a needle of such a length as will be sufficient to reach the seat of the disease, and at the same time extend so far from the surface of the skin as to keep the moxa about one inch from it. The needle is then introduced, and the moxa is now put in a state of combustion, and the heat disengaged from it is communicated to the needle, and thence conveyed to the seat of the disease." [ACUPUNCTURE.] When the pain from the third mode of applying the moxa is very great, a linseed-meal poultice will generally mitigate it, or liquor ammonia.

Prejudice against this remedy, on account of its apparent severity, has prevented its being extensively used, but almost all practitioners who have made trial of it can attest its efficacy. It will rarely be had recourse to, except in cases of a neuralgic or paralytic kind of such obstinacy or painfulness as to justify the measure; but in such diseases it should not be overlooked. Its application has dispersed the almost ossified nucleus of a goitre, which resisted all other means to effect its absorption. (Wallace, *On the Action of Moxa*.)

MUCAMIDE ($C_{12}H_{12}N_2O_{12}$). This body is produced by adding ammonia to mucic ether. It is a white crystalline substance, very slightly soluble in boiling water.

MUCATES. [MUCIC ACID.]

MUCIC ACID ($C_{12}H_{10}O_{14}, 2HO$). This acid is formed by the action of dilute nitric acid upon gum arabic, or sugar of milk, and some other bodies. One part of sugar of milk is heated with 4 or 5 parts of nitric acid diluted with half its weight of water; after effervescence has ceased, the liquid deposits mucic acid on cooling.

Mucic acid is a white crystalline powder, which is gritty between the teeth: its taste is slightly sour. It dissolves in 6 parts of boiling water, and the solution reddens litmus-paper. It is insoluble in alcohol, and dissolves very sparingly in dilute acids; it dissolves in concentrated sulphuric acid, imparting a crimson colour to it. When the mixture is heated, charcoal is developed. When submitted to dry distillation it blackens, and *pyromucic acid* and other products are obtained.

The alkaline mucates are soluble in water, whereas those which contain an alkaline earth, or a metallic oxide, are insoluble. These salts are all decomposed by the mineral acids: they combine with the base and set the mucic acid free. Boiled with water mucic acid yields the isomeric *paramucic acid*.

MUCIN. A proteic substance found in crude gluten.

MUCOVINIC ACID ($C_{16}H_{14}O_{16}$). An ethyl derivative of mucic acid, bearing the same relation to that acid as sulphovinic acid holds to sulphuric acid. [ETHYL.]

MUCUNA PRURIENS, or COWITCH, the *Medical uses of*, will be found under that head in NAT. HIST. DIV.

MUDAR, the *Calotropis Gigantea* of Brown, and the *Calotropis mudarii* (Buch.), *Asclepias gigantea* of Linnaeus. Mudar is a plant common in sandy places in many parts of India; it has a milky juice in its stem, which, as well as the bark of the root, enjoyed such reputation among the native practitioners as a medicinal agent as to lead to its use among European practitioners in the East. It was found to be very efficacious in the cure of many obstinate cutaneous diseases, such as lepra Arabum and elephantiasis: in syphilitic complaints also and anasarca, it proved so valuable an alterative that it received the name of vegetable mercury. Some use the powder of the bark of the root, but Sir Whitelaw Anslie prefers the dried milky juice, which in a recent state, if taken in large quantity, is poisonous. It was thought to possess some specific quality, but Dr. Duncan, by whom extensive trials were made of it in Britain, showed that this is not correct, but that it is infinitely more valuable from its common medicinal properties, which correspond in every respect, according to him, both in kind and degree, with those of ipecacuan. He even thought that, from the facility with which any quantity could be procured from the province of Bahar, the use of the Brazilian ipecacuan might be altogether dispensed with in our East Indian settlements.

Besides its practical value as a medicinal agent, the bark of the root possesses the singular property in one of its constituents, *Mudarine*, of being very soluble in cold water, gelatinising when the solution is heated to 85° or 90° Fahr., and recovering its fluidity on cooling. It is almost the only instance known of any organic body being an ex-

ception to the general law of the power of solvents being increased by an increase of temperature, as most albuminous substances are solidified by heat. For this reason we here describe the mode of obtaining it, and give a brief sketch of its habitudes. Mudarine is obtained in a state of considerable purity from the tincture of mudar, by macerating the powder of the root in cold rectified spirit. The greater part of the spirit may be recovered by distillation, but the remaining solution, which acquires a much deeper colour though it remains perfectly transparent, is allowed to cool. As the temperature falls, a white granular resin is deposited by a species of crystallisation from a transparent coloured solution. The whole is allowed to dry spontaneously, in order that all the resin may concrete. The dry residuum is then treated with water, which dissolves the coloured portion, and leaves the resin untouched. It is to this principle, dissolved by cold water from the resinous extract, that the name Mudarine is given. It has no smell, and is intensely bitter, with a very peculiar nauseating taste. It is exceedingly soluble in cold water at the ordinary temperature of the atmosphere, but insoluble in boiling water. It is soluble in alcohol, but the power of this solvent is increased by increase of temperature. It is insoluble in sulphuric ether, oil of turpentine, and olive oil.

It is in the solution in water when nearly saturated that the peculiar property of Mudarine is most easily exhibited. At ordinary temperatures this solution is quite fluid and transparent. When heat is gradually applied, already at 74° Fahr., a change in its constitution begins to be observable, indicated by a slight diminution of its transparency. As the temperature is raised these changes increase, and at 90° it has in a great degree lost its transparency, and has acquired the consistence of a tremulous jelly. At 95° it is fully gelatinised, and a separation of it takes place into two parts, a soft brownish coagulum, and a liquid nearly colourless. At 98° the coagulum is evidently contracted in size. At 130° the coagulum seems to dissolve: at 185° the coagulum is very small, and has a tenacious, pitchy consistence. At 212° little further change occurs. The alterations which in this state it undergoes on cooling deserve to be noticed. At 140° the fluid is very turbid: the coagulum has not diminished in size, and is now very hard and brittle. At 110° fluid less turbid, coagulum remarkably brittle, with a resinous fracture: at 100° fluid more transparent. When cooled down even to the freezing temperature the coagulum remains unaltered, and very much resembles colophony; but after the lapse of several days it gradually liquefies in a portion of fluid in contact with it, without passing through the intermediate state of a jelly.

(Ainslie, *Materia Indica*, vol. i. p. 486; Duncan in *Edin. Med. and Surg. Journ.*, July, 1829; and in *Trans. of Royal Society of Edinb.*, vol. xi. p. 433.)

MUDARIN. The name given by Dr. Duncan to a peculiar principle obtained from the bark of the root of the *Calotropis Mudari*, and to which he attributes its emetic effects. It is procured in the state of a brown, transparent, extractiform mass, by evaporating the alcoholic tincture of the bark. It is very soluble in water and in alcohol, but insoluble in ether, oil of turpentine, and fixed oils. Its aqueous solution gelatinises at 95° Fahr., coagulates at a higher temperature, and separates into a porous substance, which, when once cooled, does not redissolve for some days.

MUEZZIN, in Mohammedan countries, is the general appellation of those officers or clerks of the mosques whose duty it is to cry out from the minaret gallery the invitation to prayers, at the five canonical hours, namely, at dawn, at noon, at four o'clock in the afternoon, at sunset, and at night-close. The muezzin cry is a substitute for bells, which are not used in Mohammedan countries. The call is:—"God is great; I attest that there is no other God but God. I attest that Mohammed is the prophet of God: come to prayers; come to the temple of salvation. God is great; there is no God but God." Each of these sentences is repeated several times in succession, with pauses between, and in a kind of slow chanting, and occasionally shrill tone, forming a solemn though wild melody, peculiarly impressive, especially when suddenly breaking upon the silence of the night. On hearing the muezzin's call, the devout Mussulmans turn their faces towards Mecca, and recite their namaz, or prayers.

MUFFLE, a vaulted flat-bottomed earthen vessel in which substances may be strongly heated, and at the same time protected from the contact of the fuel; in this smaller vessels are placed containing the substances to be acted upon.

MUFTI, the general denomination of the head doctors of the law in Turkey, of religion and (where the law is founded on the Koran) of whom there is one in every large town. The mufti of Constantinople is the highest in rank, and has a jurisdiction over the muftis of the provinces, and also above the medressés, or colleges, and generally over the whole body of the ulemas, priests, or lawyers. He is styled sheikh ul islam, or "chief of the elect," and is consulted in important matters of law. He is appointed by the sultan, who can also depose him. His secretary, called fetwah emine, has an office with about twenty clerks for the despatch of business. The dignity of sheikh ul islam is one of the principal in the empire, and is equal in rank to that of grand-vizir. His dress is of white ermine.

MUGGLETONIANS. [MUGGLETON, in *BIOG. DIV.*]

MULBERRY, BLACK, *Medical uses of.* The fruit (popularly, but

incorrectly, termed a berry, being botanically a sorosis) of the *Morus niger*, is officinal in Britain. It is formed by a partial union of the enlarged and fleshy calices, each calyx enclosing a dry membranous pericarp. It is at first green, then red, and at last of a deep violet black, and contains much juice of a like colour. It has much mucilage, an astringent resin, sugar, which gives it a sweetish taste, an acid, termed tartaric by some, malic by others. The officinal form is a syrup, to prepare which the fruit should be gathered before it is quite ripe. Tin or copper vessels, or any dish lined with either of these metals, should be avoided in making it—porcelain vessels are best. A vinegar, similar to raspberry vinegar, may be prepared with this fruit, which, like the syrup when mixed with water, forms a pleasant, cooling, refrigerant drink in febrile diseases, or as a gargle in simple inflammatory sore-throat. But the syrup is chiefly used as a colouring ingredient. The fruit is susceptible of many other uses, economic and domestic. Too free indulgence in the fruit, even when fully ripe, is liable to cause diarrhoea. Many of the fruits drop from the trees long before they are ripe, and are apt to be picked up and eaten by children. No unripe fruit causes such severe griping. An emetic followed by rhubarb is necessary. The root of the mulberry is anthelmintic.

The wood of the *Morus tinctoria*, Linn. (*Broussonetia tinctoria*, Kunth; *Macluria aurantiaca*, Nutt.) contains a valuable colouring principle, which Chevreul has termed morin. The *Bois jaune* is the French name of this tree. (See Chevreul, 'Leçons de Chimie appliquée a la teinture'.)

MULE; MULE-JENNY. [COTTON MANUFACTURE.]

MULIER. [BASTARD.]

MULLET. [HERALDRY.]

MULLION (by some supposed to be a corruption of *munition*, from the Latin *munio*, to defend or strengthen), a term in Gothic architecture applied to the upright bars, or stone shafts, dividing the general aperture of a window into secondary openings, which are again in Perpendicular or Third Pointed windows frequently subdivided vertically by a similar shaft crossing the mullions horizontally, and therefore called a *transom*; whereby the whole space beneath the head of a window (supposing it to be an arched one) is formed into a series of pannels in which the glass is fixed, and which are sometimes technically distinguished as *lights* or *days*. Except in very small windows not exceeding in width one such *light* or compartment, mullions invariably occur in Gothic windows, being in fact absolutely necessary when no other mode of glazing was practised than that of small panes set in lead, because without some kind of strengthening or support, either by stone or metal rods, a spacious surface of the kind would be damaged by a strong wind, whereas each division becomes a separate window of no greater width than a single small one: consequently the number of the mullions depends upon the width of the window. Two-mullioned and three-mullioned windows are the most usual in ecclesiastical architecture, except for the large east or west windows in churches, or windows of nearly equal dimensions in other buildings. In these they are frequently very numerous; that, for instance, in the façade of York Cathedral is divided into eight lights or compartments by seven mullions, while that above the entrance to Westminster Hall has eight mullions. Again, the former of these is *untransomed*, but the other is *transomed*, being divided in its height to the spring of the arch into two tiers of arch-headed compartments; it also affords an instance of what is by no means uncommon in third pointed buildings of principal and subordinate mullions, being divided by two larger mullions into three leading compartments, each of which contains three smaller ones. The lesser or simple mullions, sometimes described as those of the *first order*, consist of the mouldings which run into and form the cusps, where the heads of the compartments are foiled; while the larger ones have additional mouldings. In explanation of this we may refer to the window from Kirton Church, at col. 443, *GOTHIC ARCHITECTURE*, where the centre mullion is larger and composed of more mouldings than the other two, which have only those that form the cusps. As far as they go, the other specimens of windows given in that article will further exemplify the subject of mullions, and serve to render it evident that unless windows were so divided it would be impossible that their heads should be filled up with tracery.

* **MULTINOMIAL.** [POLYNOMIAL.]

MULTIPLE, SUBMULTIPLE, MULTIPLICATION. Any number of equal magnitudes added together give a multiple of any one among them. Thus 4 + 4 + 4, or 12, is a multiple of 4. And submultiple is the inverse term to multiple: thus 12 being a multiple of 4, 4 is a submultiple of 12. The term submultiple is equivalent to ALIQUOT PART.

The derivation of the word is from multi-plex, mani-fold, and multiplication is the process of forming a multiple. Thus to multiply 184 yards by 279 is to repeat 184 yards 279 times, and to add all the results together. And this is the first and fundamental meaning of multiplication. Its usual symbol is $\times$: thus 4×3 is 12.

If we look at the primary rules of arithmetic, we shall see that multiplication is the only one which cannot be entirely performed upon concrete quantities. To or from 100 yards 50 yards can be added or subtracted, and 100 yards can be divided by 50 yards; but 100 yards cannot be multiplied by 50 yards. The very definition of multiplica-

tion requires that every question should contain a number of *times* which another number, abstract or concrete, is to be repeated; and this number of times or repetitions cannot be a number of anything else. Thus, to talk of multiplying 10 feet by 7 feet is a contradiction in terms; if it mean that 10 feet is to be multiplied by 7, or that 7 repetitions of 10 feet are to be made, 10 feet is multiplied *seven* times, not *seven-feet* times. But if it be meant that 10 feet is to be repeated as often as 7 feet contains *one* foot, the question has three data, and belongs to a class which will be considered in PROPORTION: it is in fact a question of multiplication in which the number of repetitions is not given, but is to be extracted from the result of a question in division. On this subject see also RECTANGLE.

It being now distinctly understood that a number of times or repetitions is an essential element of every question of multiplication, the extension is obvious by which a fraction of a time, or a fraction of a repetition, is allowed to enter. Thus $12 + 12 + 12 + 6$ is 12 repeated three times and half a time, or 12 multiplied by $3\frac{1}{2}$ is 42. Similarly $2\frac{1}{2} + 2\frac{1}{2} + 2\frac{1}{2} + 1\frac{1}{2}$, or $8\frac{3}{4}$, is $2\frac{1}{2}$ taken $3\frac{1}{2}$ times. Up to this point there is no violation of etymology; the *multiplicand* (*multiplicandum*, number to be multiplied) is taken manifold times. But [NUMBER] by the same sort of extension of language by which 1, and even 0, are called numbers, the mere exhibition of a multiplicand is called multiplying it by one: thus 7 is 7 taken once, or 7 multiplied by 1, though, etymologically, multiplication does not take place. Again, when the half of a number is taken, or when it is taken half a time, it is said to be multiplied by $\frac{1}{2}$; and so on for any other fraction. The advantage of such extension in practice more than counterbalances its obvious defect, namely, that the beginner must, without great care, be confused by the application of a word in a sense diametrically opposed to its literal meaning.

The abbreviated process of multiplication rests upon the following principles. (1.) If the parts of a number be multiplied, and the results added together, the whole is multiplied; thus 18, composed of 13 and 5, is taken 7 times by taking 13 and 5 each 7 times, and adding the results. (2.) Multiplication by the parts of any number, and addition of the results, is equivalent to multiplication by the whole: thus 13 taken 7 times and 8 times gives two products, the sum of which is 13 taken $7 + 8$ or 15 times. (3.) Successive multiplication by two numbers is equivalent to one multiplication by the product of these two numbers: thus 7 taken 3 times, and the result taken 4 times, is 7 taken as many times as there are units in 4 times 3, or 12 times. (4.) If one number be multiplied by another, the result is the same if the multiplicand and multiplier be changed: thus 7 times 8 is the same thing as 8 times 7. (5.) In the decimal system, the annexing of one cipher multiplies by 10, of two ciphers by 100, &c.

The application of these principles requires that, in the decimal system of notation, the products of all simple digits up to 9 times 9 should be remembered: this is usually done by learning what is called the multiplication table, and this table, which is only absolutely necessary up to 9 times 9, is usually committed to memory up to 12 times 12. This being supposed to be done, we shall now show the process of multiplying 1234 by 5073. By (2.) we must take 1234, 5000 times, 70 times, and 3 times, and add the results. To take 1234, 3 times, we subdivide it into 1000, 200, 30, and 4, each of which taken 3 times, and the results added together, gives

3000
600
90
12
3702

from which process the rule for multiplying by a single figure may easily be derived. The next step is to take 1234, 70 times, that is, first 7 times, and the result 10 times. The full process is

7000
1400
210
28
86380

Similarly 1234 taken 5000 times, gives 6,170,000. Now put the three results together, and add them; which gives the first column following:—

3702	1234
86380	5073
6170000	3702
6260082	8638
	6170
	6260082

The second column shows the usual manner of performing the operation, which we suppose the reader to know. We have given the preceding detail that he may do what many have never done, namely, compare the common process with the deduction of the result from first principles.

There are several abbreviations of multiplication which are very valuable, but which are not commonly taught.

1. Five times is half of ten times: to multiply by 5 annex a cipher and divide by 2: thus 76783×5 is most easily done as follows:—

2) 767830
383915

2. Nine times is one less than ten times, so that 76783×9 can be found as follows:—

767830
76783
691047

This may be best done by subtracting every figure of the multiplicand from the preceding, carrying and borrowing where necessary, in the usual way, on the supposition that the first figure is to be subtracted from ten. Thus the process of multiplying 27293 by 9 is as follows:—

27293
245637

3 from 10, 7, carry 1; 1 and 9 is 10, 10 from 13, 3, carry 1; 1 and 2 is 3, 3 from 9, 6; 7 from 12, 5, carry 1; 1 and 2 is 3, 3 from 7, 4; 0 from 2, 2.

3. Eleven times is one more than ten times; so that the addition corresponding to the preceding subtraction must be made. Thus to multiply 62781 by 11, proceed as follows:—

62781
690591

Let 1 remain; 1 and 8 is 9; 8 and 7 is 15, carry 1; 1 and 7 is 8 and 2 are 10, carry 1; 1 and 2 is 3 and 6 are 9; 6 and 0 is 6.

4. To multiply by any number from 12 to 19 inclusive, multiply by the last figure, and to the carrying figure add the figure of the multiplicand which is just done with. Thus—

2734
17
46478

7 times 4 is 28, carry 2, adding 4, or carry 6; 7×3 is 21, and 6 is 27, carry (2 + 3 or) 5; 7×7 is 49 and 5 is 54, carry (5 + 7 or) 12; 7×2 is 14 and 12 is 26, carry (2 + 2 or) 4.

5. To multiply by 25, annex two ciphers and divide by 4: to multiply by 125 annex three ciphers and divide by 8.

6. In multiplying by a number of two figures, ending with 7 or 8, as 68, it may be advisable to take the multiplicand 70 times, and subtract it twice, in preference to taking it 60 times, and adding it 8 times.

The following rules are taken from the 'Risala Hisab.' (Taylor's 'Liliwati,' Introduction, p. 17.) The first at least can easily be done without paper.

1. To multiply two numbers together, each of which is between 11 and 19; to the whole of one number add the units of the other; ten times this, together with the product of the units' places, is the product required. Thus, 17 times 14 is 21 times 10 and 28, or 238.

2. To multiply two numbers together, each of which has only two places: to the whole of one factor, multiplied by the tens of the other, add the tens of that factor multiplied by the units of the other; ten times the result, together with the product of the units, is the product required. Thus 76×38 is done as follows: 76×3 is 228, which increased by 7×8 , or 56, is 284, and 2840 increased by 48 is 2888, the answer required.

The multiplication of sums of money is facilitated by a process known by the name of PRACTICE.

The multiplication of fractions offers no difficulty when the extension of the word multiplication, already described, is understood and admitted. For instance, when we have to multiply $\frac{2}{3}$ by $\frac{4}{11}$, or to take $\frac{2}{3}$ 4-elevenths of a time, we see that $\frac{2}{3}$ being $\frac{8}{33}$ [FRACTIONS], one-eleventh of this is $\frac{8}{33}$, and 4-elevenths is $\frac{32}{33}$: whence the rule commonly given, namely, multiply the numerators together for a numerator, and the denominators for a denominator. In the multiplication of one decimal fraction by another, as 1.23 by .018, the multiplication of the numerators gives 123×18 , or 2214, and that of the denominators 100×1000 , or 100,000. But a decimal fraction which has 100,000 for its denominator, has as many places as there are in both of the others together, whose denominators are 100 and 1000. From this consideration the common rule immediately follows.

For a mechanical contrivance for expediting multiplication, see NAPIER'S RODS.

MULTIPLE POINTS. When two or more branches of a curve pass through the same point, it is called a multiple point; and this whether the branches touch or cut one another. When two or more branches intersect, it is obvious that as many distinct tangents may be drawn at the multiple point as there are branches which there intersect, that is, for one value of the abscissa the differential co-efficient of the ordinate may have more values than one. In most cases the points at which this happens may be ascertained by inspection of the equation of the curve. Thus in

$$y = (x-b) \sqrt{(x-a)+c} \quad b < a$$

$$\frac{dy}{dx} = \sqrt{(x-a)+c} + \frac{x-b}{2\sqrt{(x-a)+c}}$$

we see that y , in general, has two values, and so has $\frac{dy}{dx}$: to each value of the former belongs one of the latter. But in the single case of $x=b$, both values of y become equal, or y has only one value; while $\frac{dy}{dx}$ has the two values $+\sqrt{(b-a)}$ and $-\sqrt{(b-a)}$. There is then a

multiple point when $x=b$ and $y=c$; and as two branches cut one another, it is called a *double point*. Similarly, had there been three, four, &c. branches, it would have been called a triple, quadruple, &c. point.

It is not worth while to enter here on the general method of determining double, &c. points. (See 'Lib. Usef. Kn.', 'Differential Calculus,' p. 182.)

MULTIPLICATION. [MULTIPLE, &c.]

MUMMY, a name derived from the Persian and Arabic word *mom*, signifying wax; or even possibly contracted from the Greek word *amomom*, introduced into use about the 15th century, expressive of an embalmed or dried body, either of a man or animal, preserved, by resinous gums, wax, or salt, and even desiccation, from decay. The Egyptians themselves called such bodies *sahu*; and the word *Gabbara* used by St. Augustine (Serm. cccxi, 12), is probably the hieroglyphic *kheper*, or "transformation," a term sometimes applied to the dead. The reason of thus preserving the body is involved in great obscurity, and its origin can be traced to the very earliest existence of the Egyptians. According to the classical authors, the welfare of the soul and its protection from the palingenesia, or transmigration, depended on the preservation of the body to which it returned after the accomplishment of its cycle of existence of 3000 or 10,000 years. (Servius ad Virgil. 'Æn.' iii. 67.) The Egyptians had also great horror of the body being devoured by insects, or burnt by fire. It has been also conjectured that physical reasons may have introduced the custom, it being impossible to bury the dead in an alluvial soil annually flooded, or deposit them unembalmed in hills adjacent to cities, loading the air with infectious vapours. (Rosellini, 'Mon. Civ.' iii. p. 310; 'Casiodorus Coll.' 15, c. 3.)

The hieroglyphical inscriptions throw some light upon Egyptian notions, showing that it was an object of solicitude that the soul should depart from earth, and that the body should remain or endure in its sepulchre. According to the sepulchral ritual (Lepsius, 'Todtenbuch,' taf. xxxiii, c. 89), the soul revisited the mummy, and if this wasted or decayed the soul immediately transmigrated. (Lepsius, 'Todt.' taf. lxxv, c. 154.) In the moral nature of man, the hieroglyphical legends assert that the soul is the good and immortal principle, while the body is the bad and perishable (Rosellini, 'Mon. Civ.' iii, p. 330); but every care was taken that physical means could devise, or theological ingenuity invent, to prevent the mortal frame from being destroyed. The corpse was embalmed after the model of that of Osiris; and the invention of the art was ascribed to his son Anubis, who first performed this office for his father. At Philæ the wall paintings represent the embalment of Osiris; and other paintings in the tombs show the embalmers engaged in their occupation, the bodies ready for embalment, the bandaging of mummies, and the preparation of the funeral equipment. (Rosellini, 'Mon. Civ.' tav. cxxv.) The following were the rites of this art:—Immediately on the death of a person the relations, male and female, of the deceased raised throughout the city the funeral wail. The body, if a female, was retained a few days at home; those of males were delivered at once to the undertakers, called by the Greeks *Paraschistæ*, or "flank incisors," a polluted class, who were excluded from entrance into the temples, and even obliged to reside in the cemeteries or the suburbs of the great cities. (Strabo, xvii. 1145; Manetho, 'Apotelesm.' vi. 549.) These *paraschistæ* had at the time of the Ptolemies the right of incising the corpses of particular districts, and several papyri attest their contracts or record their litigations. The principal Greek authorities (Herodotus, ii. 85, 87; Diodorus, i. 91) have given rather discrepant accounts of the offices of the *paraschistæ* and *taricheutæ*, but the following appears to have been the mode of embalming in their days. After the corpse had been transported to the establishment of the embalmers, a scribe drew with a reed on the left side, below the ribs, the line of the incision to be made by the *paraschistes*. One of that fraternity then, with an "Æthiopic stone," a kind of rude knife of flint or obsidian, made the necessary wound, and was immediately pursued by the bystanders with stones and imprecations, as if he had committed a heinous crime. Another of the embalmers, probably one of the class called *taricheutæ*, or "picklers," then proceeded to draw or remove the entrails and thoracic viscera, leaving only the heart and kidneys in the body. The viscera were soaked with palm wine and aromatic drugs; or, according to Porphyry ('De Abst.' liv. iv, c. 10), the viscera were placed in a vessel and thrown, as the causers of impurity, into the Nile, after an appropriate prayer. Other embalmers, or *taricheutæ*, proceeded at the same time with the extraction of the brain, which was removed with a crooked instrument of bronze, resembling a catheter, through the nose, in order to deprive the body of the soft portions, which were most liable to decay, and enable them to confine their operations to the preservation of the skin and muscles. The subsequent operations depended upon the wealth and taste of the friends of the deceased. In the age of Herodotus three modes of embalming prevailed, models of which were

shown by the *taricheutæ* in their shops to the relatives of the deceased. In the first process, which cost a talent of silver (about 243*l.* 15*s.*), used only by the wealthiest classes, certain drugs were introduced into the vacant cavity of the skull through the nostrils, the belly was bathed or rinsed with palm wine, and afterwards filled with powdered resins, cassia, and other aromatic drugs, and then the flank incisions sewn up. After the body had been plunged into natron for 70 days, it was wrapped up in linen bandages, anointed with gums which the Egyptians used instead of glue, finally placed in a wooden coffin, and set upright against the wall, either in the home of the deceased or in a mortuary chapel. For persons of more moderate means a cheaper process, costing only 20 minæ (81*l.* 5*s.*), was employed; the brain was apparently removed, but the *paraschistes* was not called in to make the flank incision, the viscera being injected with oil of cedar, and the body steeped in natron for 70 days, after which the viscera came away, and the skin and bones only remained. The third process cost a trifling sum, not mentioned, and was used only by the poorer classes; the body was washed with myrrh, and salted for 70 days. (Herod., ii. 87.) Diodorus, indeed, makes the period only about 30 days, but the longer period seems more correct.

When the body was finally prepared, the mummies were delivered to their families; but it sometimes happened that a considerable time elapsed before they were finally committed to the tomb, and they were till then retained at home (Cicero, 'Tuscul.' i. 45; Tacit. 'Hist.' v, 5, 7; Mela, i, c. 9), and sometimes produced at festive entertainments (Lucian, 'de Luctu,' 21). Even as late as the days of St. Athanasius, A.D. 325, mummies were kept at home on couches (Athan. 'Vita Anton.'), a custom which was reprobated by the fathers of the church. (Damasc. Or. i. 'de Imag.'; St. Hieronym., vita St. Hilarion, c. 40.) During the period of their embalming and mourning the relations abstained from the use of the bath, of wine, and of delicate food, and arrayed themselves in mourning or coarse garments. When finally committed to the sepulchre, the mummies were confided to the care of the *Cholchytæ*, a class of priests of higher rank than the *taricheutæ*, or embalmers; they were deemed a respectable fraternity, admitted into the temple, and enjoyed the privilege of sanding the floor. (Peyron, 'Papiri Greci,' i. p. 62.) It has been supposed that they wrapped the mummies in linen bandages, after the model of Osiris (Athenagoras, 'Legat. pro Christ.' 29; Damasc. in 'Phot. Bibl.' cod. cexli; Suidas, 'voce Heraiskos'), but this is hardly probable, as females belonged to the class. (Peyron, 'Pap. Greci,' 1827, ii. p. 48–64.) They rather appear to have inhabited the Thynabouna, and the Memnoneia, or necropolis on the western bank at Thebes, and to have been engaged in celebrating the funeral masses of the mummies, to which certain emoluments were attached, and which they sold with the houses they occupied and the mummies under their charge. Many papyri contain their plaints: one, A.D. 127, records the injuries and thefts perpetrated by resurrectionists on the funeral paraphernalia of their mummies to the amount of about 28*l.* or 72*l.* (Letronne, 'Nouvelles Annales,' i. p. 273; Kosegarten, 'Bemerkungen ueber ein Ægypt. Text. eines Papyrus,' 4to, Greisf. 1824); and it appears from the document that the doors of the sepulchre had been left open, and the mummies themselves become the prey of prowling jackals. The mummies were sent in funeral barges or *baris* down the Nile to their sepulchres, the poorer shipping them on board the public vessels, and merely attaching to them a tessera or ticket of wood; while richer individuals hired a private *baris*, and despatched a messenger with a letter describing the private marks on the bandages by which they might be recognised. (Peyron, B., 'Papiri Greci,' p. 40.)

Not only were the bodies of the Egyptians thus embalmed, but those also of persons who died in the country were subjected to the same process. One of the earliest embalmments on record is that of the patriarch Jacob, who was prepared in this manner for 40 days. (Gen. i. 3.) Joseph was also, according to the rabbinical writings, embalmed and buried either in the bed or on the banks of the Nile. (Gen. i. 26; Isaiah, lxxv. 4.) The body of Alexander the Great was embalmed with honey (Statius, 'Silv.' iii, 2, 116), and existed at Alexandria till the age of the Emperor Severus, and was seen and handled by Augustus on his visit to that city. (Dio., li. 16.) The bodies of Antony and Cleopatra were embalmed in the Egyptian manner, and deposited in the same sepulchre, and that of the unfortunate queen was subsequently found entire by the Emperor Heraclius. ('Epist. ad Sophocl.') Embalment was also the right of the poorest Egyptians, even of malefactors; and those who were injured by crocodiles were treated with remarkable honour, and buried at the expense of the nearest city. The Æthiopians, according to Herodotus (iii. c. 24), embalmed in nearly the same manner as the Egyptians; they appear to have coated the body with lime, and to have placed it in a sarcophagus of glass or some other transparent substance, and after keeping it about a year in their houses, and offering and praying to it, to have finally placed it outside the city.

It is clear that in the space of more than 2000 years the mode of preparing mummies must have greatly differed, and that individual caprice must have been often exercised in so empirical an art. The older writers (Lanzon., 'de Balsamatione,' 12mo, 1693) divided them into six kinds, but the more recent observers have considered the art as:—1. Drying the bodies in the sand, chiefly employed for the poorer classes (Magnus, 1, 'das Einbalsamiren,' p. 26; Belzoni, 'Discoveries,' p. 170); 2. Salting in natron, and then drying; 3. Boiling in resins and

bitumen; 4. Preparing with fine resins, and removing the brains and viscera. A division, purely arbitrary, has been made between mummies having the flank incision, and those without. Of the 1st class they make:—1. Those prepared with an aromatic resin, having the skin like tanned leather, sometimes partially gilded; 2. Those prepared with bitumen, the skin hard and shining like Japan varnish, the body filled with bitumen, the mummy difficult to unroll. Of this class some are salted and then daubed with resinous substances, others with pitch, having the skin hard and smooth. The mummies without the flank incision are either salted and prepared with impure masses of bitumen, or salted only; the first kind have their form utterly destroyed, being covered with a mass of pissasphalt which has penetrated through the skin, muscles, and bone, owing to their having been boiled or suffused with bitumen. They are hard, and give forth a pleasant smell, and they chiefly come from Sakkara, and date from the 7th to the 2nd century, B.C. The salted mummies are usually in bad condition, the skin like parchment, and easily broken. Some anomalous examples have been found prepared with wax, and in those prepared by pissasphalt the skin has been sometimes removed. (Magnus, 'das Einbals. d. Leichen,' p. 26-27.)

Great difference of opinion exists about the substances employed, *natron* or *litron* is supposed to be Glauber's salts, common salt, saltpetre, or soda (Dioscorides and Galen), kedrion, or oil of cedar, turpentine, or pyroligneous acid (Pliny, 'N. H.' xvi, c. 21; Lösch, 'die ägypt. Mum.' 12mo. Nurenb. 1827.) Asphalt came from the Lacus Asphaltites of Idumaea (Diodor., xix. 99; Strabo, xvi. 526), the pissasphalt was a mixture of the same substance with pitch. Myrrh and cinnamon (the bark of the *Laurus cassia*, (Herod., ii. 87; Magnus, p. 33.) The *symsea* was an alkaline preparation. All these materials have been found in different mummies, either within or without the bodies, and some mummies have been found strewn with the drier materials, such as myrrh, cinnamon, and cassia, which retained their fragrance. (Osburn, 'Leeds mummy,' p. 6.)

Considerable difference prevails as to the treatment of the various portions of the body: the brain was generally removed through the nose, or orbits of the eyes, or base of the cranium. The cavity of the skull when removed is found sometimes hollow, at others filled with pissasphalt, or earthy matter. The nostrils are generally plugged with linen pads to exclude the entrance of the air, or of destructive insects, which nevertheless have sometimes penetrated the skull and body. The eyes have sometimes been removed and the cavities filled with artificial ones of ivory and obsidian or coloured porcelain. The hair of men has generally been left in its natural condition, but that of females has often been cut off, wrapped up in separate linen bandages, and deposited either in the coffin, or placed on the body. Sometimes these masses of hair are made up in an oval shape and covered with bitumen, at others merely folded in linen. The flank incision varies in position and length, being placed in some mummies beneath the ribs, but in others under the arm-pits. This incision in mummies of the 26th dynasty, and under the Ptolemies and Romans, has a square rectangular thin plate of tin, on which is incised in outline the right symbolical eye, emblem of the sun, in accordance with the 140th chapter of the Ritual. (Lepsius, 'Todt.,' taf. lvii. c. 140.) The entrails, which have been removed through this incision, have been treated in different manners, according to the care with which the embalmment has been performed, or the epoch at which the body has been mummied. At all epochs the most costly funerals had four large jars of zoned, alabaster, calcareous stone, terra cotta, porcelain, or wood modelled in shape of the four genii of the dead,—*Amsat*, *Hapi*, *Tuautmutf*, and *Kabhsenuf*; mummied, and having the heads of a man, ape, jackal, and hawk. The thoracic and abdominal viscera were divided into four portions, embalmed in accordance with the process employed for the body, either by immersion in natron, or boiled in asphalt, made up into oval or cylindrical packets which are enwrapped in linen, and one portion deposited in each jar. On the day of the funeral these jars were placed in a large box and transported on a sledge to the sepulchre, and finally arranged at the side of the coffin or under the sepulchral bier. The most elegant and costly jars have formulæ reciting that the four principal goddesses, Neith, Selk, Isis, and Nephthys, watch over and protect these embalmed portions. In mummies of a later period, where so much cost was not expended, the embalmers made the viscera into four oval packets, and either placed them on the body, or returned them through the flank incision into the body, in which case they are usually accompanied by figures of red, yellow, or dark wax, or earth coated with that substance, representing the four genii. On a mummy opened at Jersey (Pettigrew, 'Archæologia,' vol. xxvii. pp. 262, 273), the portions attached to *Amsat* were the stomach and large intestines, *Hapi* presided over the small intestines, *Tuautmutf* the lungs and heart, *Kabhsenuf* the liver and gall bladder. Mummies of the 26th dynasty have sometimes the fingers enclosed in stalls of silver, in order to prevent injury to the nails when the epidermis was destroyed, and the body subjected to the boiling bitumen into which the body was immersed (Birch, 'Archæol. Journ.,' viii. 278); and in the days of the Ptolemies and Romans, the tips of the nose, the nails, and extremities, and even portions of the flesh were gilded, supposed by some to be those parts where decay had commenced, or lesion appeared. (Gryphius, 'Mum. Wratisl.' 12mo. 1662; Fabricius, 'Biblogr. Antiq.' c. xxiii. i, c. 7.) One

particular custom, not Egyptian but Greek, is found on mummies of the Ptolemaic and Roman period—the jaws are carefully closed and bound up, while in those of the Pharaonic age the mouth is always open. (Cailliaud, 'Voyage à Meroe,' iv. p. 13, and foll.) The mummy of Petem-enophis-Ammonios, found by Cailliaud at Gournah, was discovered to have the eyelids closed by a plate of gold in shape of an eye with its lid, and a plate of gold in shape of the tongue over that member, while a crown of gilded copper encircled the head. (Cailliaud, pl. lxxi.) On the Wratislaw mummy, a plate of gold of 10 grs. weight was found under the tongue. (Gryphius, p. 46.) The limbs are differently disposed, the legs, however, always straight and extended; the hands of women are sometimes crossed upon the breast, and of girls on the groin; those of men and women are often placed flat down the sides, with the palms inwards and fingers extended. (Cailliaud, 'Voy. à Mer.' iv. 13; Passalacqua, 'Cat.' p. 180.) Various small portions of the body, such perhaps as had become diseased, were embalmed separately in the same manner as the viscera, and placed in recesses hollowed in the pedestals of wooden figures, in shape of Osiris, or Ptah Socharis. (Rosellini, 'Mon. Civ.,' tom. iii. p. 349.) The hieroglyphical Ritual gives directions for various amulets to be placed about the body, the most remarkable of which are a scarabæus of hard stone inscribed on the base with the 26 or 64 ch. found on rich mummies on the breast; or when plain, sometimes discovered inside the body: this was to protect the heart. Another in shape of the index and middle finger is often found in the belly. (Pettigrew, 'Hist. Eg. Mum.,' pl. iv. 5, p. 96; Herzog, Pl. fig. 34.) The other amulets, chiefly disposed on the neck, are a pillow of hematite, emblems of life, of stability, symbolic eyes, and figures of deities strung as a necklace round the neck. Nineteen were found on the Jersey mummy, and seventy-four on that of Gotha. Plates of tin incised with the winged disk, or the flying hawk, and other symbols, have been found on the chest. Besides these amulets, the jewellery worn during life, the ear-rings, bracelets, finger-rings, collars, and other valuables, have constantly been found. (Herzog, 'Mumiogr.' p. 16.)

The bandages of mummies are invariably of linen, the use of wool being prohibited. (Herod., ii. 37.) The only woollen bandages discovered were those of the supposed body of Menkheres, and of the workmen of the Tourah quarries, rendering the age of these bodies uncertain. Neither cotton nor silk, as conjectured by some of the older writers, was ever used. (Thompson, 'Mummy Cloth,' Class. Mums. vol. vi. p. 152.) The greater part of these bandages were made of old linen, either collected by the deceased during his life-time or else by the *taricheuta*. Shirts and darned portions of garments are frequently found, and even the initials of the deceased embroidered on the cloth. This cloth is of various qualities, from the coarseness of canvas to the fine texture of muslin. The mass of bandages are, however, strips of about three or four inches wide, and from one to several yards wide, wound round the form with great skill and symmetry, and apparently laid on in a wet state. All the inequalities are carefully padded with small pledgets to bring the body to a symmetrical shape. At the Roman period, the limbs are bandaged separately, showing their form, in narrow strips of linen. The bandages near the form were often laid on while the asphalt was still hot and liquid, and others were dipped in liquid aromatics before applied; but the greater part are of linen once white, but which has become of a cinnamon or yellow colour through age, although capable of resuming their original colour when bleached. Some pieces of linen have selvages, fringes, and blue lines, produced in the wool by threads dyed with indigo, as if torn from the original piece, and large shrouds which cover the other bandages close to the surface have been dyed of a red colour by means of the *Carthamus tinctorius*. The length of these bandages is considerable, as much as 1000 ells having been found wrapping a single mummy. Wrappers bandaging mummies are represented in Rosellini ('Mon. Civ.' cxxvi.). The mummy when thus prepared exhibited only the general outline of the human form, and lay like a great chrysalis in its cocoon. The name of the deceased, the years that he lived, and the reign of the monarch in whose reign he died, are sometimes found inscribed in a caustic ink, said to be nitrate of silver, on the inner bandages of some mummies. These marks are supposed to have been made in the shops of the wrappers, to prevent mistakes in the re-delivery of the bodies to the families. The bandages are generally of coarsest linen near the body, and of finer quality outside.

On some mummies, prepared with the greatest care, straps of a scarlet leather, about one and a half inch wide, have been found crossing the shoulders, the ends crossing on the breast, on the ends of which are stamped, apparently by a heated metal-punch like that used by the bookbinders, the names and titles of the reigning king, or the monarch adoring Amen-Ra. The earliest of these bears the name of Rameses XIII., of the 20th dynasty (Osburn, 'Mummy at Leeds,' pl. 2), and they continued to be used till the age of the Psammetici, B.C. 525. At the Roman period leaden and wax seals were sometimes attached to cords passed through the bandages of mummies, but the reason of the custom is unknown. (Pettigrew, 'Hist. Eg. Mum.,' pl. xi. 3.) The interior bandages of mummies have frequently a case composed of as many as twenty or forty layers of linen closely pressed and glued together, and then covered with a thin layer of lime, on which have been painted in tempera the face and dress of the mummy, various

deities connected with funereal rites, and vignettes and texts of chapters from the Ritual. A certain order attends these drawings—a scarab is often painted on the head, a flying ram-headed hawk on the chest, the goddess Nu on the stomach, and at the feet, sometimes made of a piece of board, the enemies of Egypt painted under the sandals, or the bull Apis bearing on its back a mummy. These cartonages, which are found on the mummies of the kings of the 11th dynasty, continue till the Ptolemies. Under the Roman empire they were replaced by a large painted sheet, on which was painted the deceased or Osiris, and some sepulchral deities, or by the portrait of the deceased painted upon thin boards of cedar in encaustic. These later paintings cease to preserve the conventional Egyptian style, but represent the deceased with Greek features and costume. Beneath these cartonages is found a network of blue porcelain bugles, deities, and pectoral plates, and sometimes beaded work well executed, and they are externally ornamented with wreaths of artificial or real flowers, and tinsel. The cartouche has often the same pedestal as the mummy-case, showing that the body was set upright during the funeral ceremonies. The colours employed, and the style of painting of this sepulchral ornament, is very different in different mummies and at different periods.

Sometimes instead of a cartouche the external linen bandages are covered with extracts, more or less copious, from the Ritual of the Dead, traced in black carbonaceous ink, a style of ornamentation which prevailed both at an early and recent period, having been found on the coffin of a monarch of the 11th dynasty, and on mummies of the Ptolemaic period. Figures of deities and other representations taken from the sacred books are also traced on the bandages. Papyrus were often deposited with the mummies generally rolled up, and in the inner bandages sometimes unfolded and spread over them, rarely in the hands, as in the case of a Greek mummy exhumed at Thebes, which held in its hand a papyrus containing the 17th book of the 'Iliad.' These relics were, however, often placed in wooden figures of the gods Osiris and Phtah Sochtaris. These papyrus are chiefly rituals or other religious books of a sepulchral nature. Besides papyrus, little mummified figures, called 'the workmen of Hades,' made of stone, porcelain, clay, or wood, were deposited in the tombs in little wooden boxes, to help the deceased in his agricultural labours in the Elysium. Around them is inscribed the 6th chapter of the Ritual.

The mummies in their cartonages were deposited in coffins of sarcophagi, generally of wood, either of cedar or sycamore, made in the shape of a mummy with its pedestal. Persons of high station and wealth sometimes had as many as three of these wooden coffins each increasing in size so as to fit into one another like a nest of boxes. Those of kings were deposited in an outer sarcophagus of hard stone in shape of a chest or bin. Such outer coffins are of the greatest rarity, and at the early period of the pyramids are either entirely plain or only ornamented with architectural ornaments, but in the age of the 18th and following dynasty are covered with inscriptions and intaglio reliefs representing the passage of the sun through the hours of the day or night. Some of these stone sarcophagi, especially those of the later dynasties, are in the form of the mummy. The inscriptions of those of the 26th dynasty are often the 72nd chapter of the Ritual; the stone coffins of the Ptolemaic age have the same principal deities of the Pantheon addressing the departed as Osiris, and other formulæ. The wooden sarcophagi are of different shapes at different ages—that of the king Menkheres, builder of the 3rd pyramid, is of cedar, uncoloured and in the shape of a mummy—those of the 6th & 11th dynasties are often rectangular chests painted inside with representations of wardrobes, and inscribed with copious extracts of funeral rituals.

The coffins of mummies from the 18th to the 26th dynasty are made in shape of the human form swathed, are principally sycamore covered with a ground of white stucco, and painted with various deities and hieroglyphics in tempera. Their style of art differs at each period, and vignettes of the 89th and 125th chapters of the Ritual are often seen amongst the paintings, at a later period the 99th chapter is sometimes found. The paintings of coffins of the 21st dynasty are often of a yellow colour, owing to the copious employment of varnish which has assumed this colour through age. This style of coffin apparently continued till about the 1st century, B.C. when a new shape was introduced, the body being laid upon a flat board over which is placed a vaulted cover, having at each corner a square upright post, resembling a dish cover. The paintings on these coffins are the Great Judgment, c. 125 of the Ritual; in the interior are figures of the heaven, and Greek and Egyptian zodiacs. Those of later periods were probably of the same shape, but ruder in their art; owing to the expense few mummies comparatively were placed in coffins, those in the public cemeteries being found piled in tombs one above another, while others are laid in layers of reed or charcoal, and some bodies are found buried in the sand. The tombs of the Egyptians are generally hollow rock chambers excavated in the hills of the Arabian chain to the west of the principal cities, but sometimes, as at Sakhara, in tombs hollowed in the plains. The principal sites where mummies are found are at the bournah quarter of Thebes and in the plains of Sakhara. Few mummies of children have been found. The number of mummies made from the commencement of the Egyptian monarchy till the cessation of the art in the 7th century has been calculated to have been 420,000,000. Owing to the changes which have taken place even in times of remote antiquity,

when the Cholchytæ trafficked in tombs and bodies, it often happens that the mummies and coffins do not correspond, the names of the older occupants having been erased for the new occupants, and the Arabs and other dealers have often placed mummies in the cases sent to Europe which do not belong to them (Birch, 'Epochs of Mummies' in Gliddon's 'Otia Egyptiaca,' p. 78-87; Passalacqua, 'Catalogue,' p. 181.) Several mummies exist in the different collections of Europe, and reference to the principal ones described will be found in the works cited in this article.

In unrolling mummies, the cartouche or outer covering should, when necessary, be carefully divided vertically from head to foot in order not to destroy the interesting paintings with which it is covered, and the bandages unwound with care, every one being carefully examined to see all the peculiarities which may occur. The body itself requires a medical autopsy. Deception has been occasionally practised, many fictitious mummies made by Arabs or Levantine traders having been detected by Blumenbach. ('Observat. on Mumm. Phil. Trans., 1794.)* In the 15th and 17th centuries, the pissasphalt and other resinous substances which exuded from mummies were employed as a drug called mummy, the Genoese and Venetians extensively imported mummies into Europe for the shops of the apothecaries, and the charlatans of the day obtained from mummies, oils, extracts, and elixirs, antidotes of all poisons and nostrums against all diseases. Francis I. always had this universal remedy about him.

The Egyptians applied the art of embalmment to the preservation of the bodies of the sacred animals, so extensively worshipped throughout Egypt from an early period of the monarchy, although they did not bestow upon them so much care as on the human mummies. The mummies of apes, cynocephali, the living emblem of the god Khons, have been found in catacombs at Thebes, prepared by natrons and resins, and adjusted in a squatting, not extended form like human mummies. A dog, living emblem of Anubis, has been found mummified at full length, and some were enwrapped in cartonages. Large numbers of cats, sacred to Bast, chiefly in the extensive catacombs of these animals at Busiris, have been found, some in bandages made up into the form of the animals; others of conical shape with feet close to the body, and the head modelled in linen, and others placed in coffins of wood or bronze made in the form of small statues of this animal, with their pedestals in shape of the hieroglyphic name of the goddess to which it was sacred. It was embalmed according to Herodotus (ii. 83.) with kedria.

Wolves' mummies have been found at Lycopolis. The larger animals were only partly embalmed, the principal bones being made up into a kind of rude trunk of the animal, the head and skull carefully preserved, the bodies wrapped in papyrus or palm-leaves, and the eyes, nostrils, and diacritical marks of the sacred bulls Mnevis of Thebes and Apis of Memphis being worked in a dark or coloured cloth on the outer bandages. Sometimes their mummies have been made up in shape of a minotaur. The Apis was also in some instances embalmed with bitumen and placed in huge coffins of stone in the vicinity of the Serapeum. [SERAPEUM.] Mummies of rams and lambs, sacred to Ammon, &c., prepared by natron, and bandaged in the same manner as the sacred bulls, have been found at Thebes, and also the heads of a small gazelle *leucoryx*, treated in the same way, without bitumen. Mummies of the sacred vultures of the goddess Mut, and different kinds of falcons sacred to the sun, made up into the form of a mummified deity, with the hawks' heads modelled in linen, and the body covered by a neat network of thin linen strips, have also been found at Thebes; the owl, emblem of Buto, and the swallow have also been discovered. But the bird most commonly embalmed was the *ibis*, sacred to Thoth, extensive catacombs of it mummified existing at Sakhara and some pits of the same at Thebes. Its mummy is made in the shape of a heart, the head and neck beneath the left wing, and the beak the length of the body. According to Ælian (Nat. An., x., c. 29), it was embalmed in natron: the analysis of the materials shows them to have been salt, oil, pitch, and aromatic resins. (Langguth 'De Mumm. Avium,' 4to, Vitteberg, 1803.) The eggs of this bird, and parts of its food, have been found with it; but in most instances, apparently owing to heated applications, it has almost entirely perished. At Sakhara the mummies are found in stone, glazed ware, or terra cotta cases, or cones with convex covers, cemented with lime, and piled in the catacombs; at Hermopolis its mummy is placed in oblong cases of wood or stone; and at Thebes only in its envelopes. Some rare instances represent it bandaged as a human seated body, with an ibis head. The sacred goose of Seb also occurs. Numerous mummies of the sacred crocodile of the god Sebak have been found at Ombos, Eileithia, principally at Manfaloot, and Thebes. They are prepared with bitumen, cemented, and wrapped in palm-leaves and papyrus, having coarse outer bandages of linen. The serpent tribe are embalmed in packets in shape of an oblate egg, sometimes as many as six in one packet, the whole neatly and tightly packed with pink and yellow bandages, or single instances deposited in bronze cases in shape of the reptile on a pedestal. Lizards have been found in cases of the shape of the reptile; two species of fish, the cyprinus and the silurus; and also scarabæi, prepared by natron, and wrapped in linen bandages.

Nations of antiquity attempted to preserve the human form after death, but they can scarcely be considered mummies. The Persians

used wax (Herod., i. 140; Cicero, 'Tusc.' i. 45); the Assyrians honey (Strabo, xvi.), and the Jews embalmed their kings Asa and Zedekiah with spices (2 Chron., xvi. 14; Jerem., xxxiv. 5). The body of our Lord was anointed with spices (John, xix. 39, 40). Aristobulus was preserved in honey (Joseph., xiv., c. 7); and Alexander the Great was embalmed with wax and honey (Statius Silv., iii. 2, 117). The Romans occasionally—as in the case of Poppæa (Tacit., 'An.', xvi. 6)—embalmed the body, and bodies so prepared have been found near the Appian Way and at Albano. Certain bodies have been found dried by the effects of natural situations, as the corpses of the Spaniards and Mexicans fallen in fights (Humboldt, 'Ansicht der Natur,' 12mo, Tub. 1808, p. 509); those frozen by cold in the morgue of the convent at St. Gothard (Gannal, 'Hist. d'Embaumement,' p. 53); others discovered in 1785 in the church of the Innocents at Toulouse (Puymaurin, 'Acad. de Toul.', 1787; Magnus, 'Das Einbals.' p. 15); at Bourdeaux; in the cloisters of the Capuchins at Palermo (Smyth, 'Sicily,' p. 88); those in the vaults of St. Michan's Church at Dublin; that of Aurora, Countess of Königsmark, at Quedlinburg, others at Haliar, and at Strasburg, &c. Embalmed bodies of monarchs of the middle ages and of the last centuries have been occasionally found.

The only people who adopted a mode of preserving the body like the Egyptians are the Guanches, the ancient inhabitants of the Canary Isles. These bodies, called *xaxos*, had the viscera removed through a flank incision made by a stone called *tabona*. The belly was then filled with absorbent vegetable powder and salt; a salve of goats'-fat, the rind of figs, pitch, pumice, and a kind of euphorbium, and the *Chenopodium ambrosioides* were used in the preparation, which was continued for 14 days (Bory St.-Vincent, 'Essai sur les Isles Fortunées,' 4to, Paris, 1807, ii., p. 56; Magnus, 'das Einbals.' p. 71), the body being dried in the sun or by a stove. When thus prepared, the mummies, adjusted in a squatting position, were sewn up in sheep or goat skins; those of the poorer classes being joined together in one envelope, while those of the richer were placed in their dress *tamarco* in cases hollowed out of savine wood, and placed under a kind of pyramid. The bodies are not bandaged, but are excessively light, being quite dried and tanned, with a slight aromatic smell; the features are distorted, and not well preserved. Numerous catacombs are found filled with them, and as many as 1000 were discovered at Teneriffe. (Humboldt and Bonpland, 'Reise,' 12mo, Wien., 1825, i., 225.) On the American continent, probably owing to the greater dryness of the air, preserved bodies have been found, as at Durango, Bogata, and those of the Coroados Indians on the Paraíba River, in the Brazils, the bodies of whose chiefs, deposited with their ornaments and favourite animals, in a couching posture, in large covered jars, are long preserved. (Debret, 'Voy. au Bresil,' i. 19.) Several dried bodies of the ancient Peruvians, wrapped up in coloured cotton bandages, have been found at Arica and other places in Peru; but their preservation is due to the lightness of the soil and the air, and not to any artificial process. In the South Sea, at Nukahiwa, bodies have been temporarily preserved for a few months in cocoa-nut oil (Langsdorf, 'Reise um die Welt,' i. 208); and the Birmese know how to keep the body for a short time by means of pitch *dhamma*; but such processes scarcely render the body a mummy. It is not necessary here to detail the modern processes employed for the preservation of the body for museums of anatomy and natural history, as such embalmed bodies are in no sense mummies, and the European climates are too unfavourable to permit their preservation except under circumstances of peculiar care. The subject of mummies has been treated by many authors since the commencement of the 16th century. The principal works treating of the subject in general are—Pettigrew, 'History of Mummies,' 4to, Lond., 1834; Gannal, 'Traité d'Embaumement,' 8vo, Paris, 1838; Philadelphia, 1840; Magnus, 'das Einbalsamiren der Leichen,' 8vo, Braunsch., 1839.

MUMPS, an inflammation of the parotid, and often, at the same time, of the other salivary glands, of contagious or epidemic origin. The inflammation, and the fever by which it is accompanied, generally increase for about four days, and then begin to subside; and after four days more, the disease is commonly at an end. The affection has a tendency to metastasis, that is, to pass suddenly from the organ first affected to some other. The treatment required is very simple; quietude, abstinence, seclusion from cold, the application of poultices or other warm substances, or, in severe cases, of leeches to the swelling, are all the means that are usually necessary.

MUNICIPAL CORPORATIONS. A municipal corporation, as at present understood, may be defined to be a body politic formed for the purpose of local government. Other bodies politic or corporate exist for the advancement of religion, learning, or commerce. The municipal corporation is concerned with the regulation of the social and financial affairs of a town, or limited body of citizens. The origin of such bodies in this country may be traced to the times of the Roman occupation, that people having planted *municipia* or town-communities in this island, as in other parts of their dominions.

The Anglo-Saxons appear to have adopted these institutions, finding them entirely congenial to their previous customs, and, in fact, their municipal organisation was not confined to the towns or fortified cities alone, but pervaded the whole territory, which was divided into districts in the management of the affairs of which every freeman had a vote.

The Norman kings endeavoured to effect a centralisation of political power by substituting *bailiffs* of their own in the place of the elective *borough- or port-reves*, who during the Saxon times presided over the various town communities. To rid themselves of the oppression of these officers, the towns offered to pay a larger revenue to the king's exchequer, than was extracted from them by the bailiffs, provided they were allowed to collect it themselves. Thus the right of self-government was gradually repurchased from the crown, the obnoxious title of bailiff being in most cases done away with, and that of *mayor* adopted to designate the chief officer of a town.

For several centuries after the Conquest, a select body or corporation in the more modern sense of the term, within and distinct from the township itself, was unknown. The chief object of the Norman sovereigns in granting to the burgesses or townsmen the right of electing a chief magistrate of their own, was to obtain punctual payment of a stipulated rent, and to insure at the same time in each locality as much internal peace and order as was requisite to enable the community to perform this stipulation with exactness. The municipal body consisted of the resident and trading inhabitants, paying scot and bearing lot, that is, sharing in the payment of local taxes and the performance of local duties. Strangers residing temporarily in the town for purposes of trade had no voice in its affairs, as they incurred no liability to its burdens. Birth, apprenticeship, or marriage within the township, were titles to citizenship, as evidences of the essential requirement of established residence. Titles by purchase were obtainable by individuals not previously connected with the community, or who were permanently resident elsewhere. In many of the greater towns, the subdivision of the general community into *guilds* of particular trades, called, in many instances since the Norman era, *companies*, opened up avenues for admission to the general franchise of the municipality. In their greatest prosperity these fraternities, more especially in the metropolis, were important bodies, in which the whole community was enrolled; each had its distinct common-hall, made by-laws for the regulation of its particular trade, and had its common property; while the individuals composing them, as members of the great general community, remained the same.

In course of time, and after the practice had arisen of the towns sending representatives to take counsel with the king in parliament, it became the policy of the crown to give a more distinct entity to the governing powers in the various boroughs, and to form close bodies, irresponsible to the general community. In most cases, by an arbitrary stretch of power, the various guilds were dissolved, and their property confiscated and transferred to the newly-constituted corporation. Such bodies were found to be infinitely more manageable than the freemen, and by their means a great influence was obtained by the sovereign in the appointment of representatives. This policy was pursued by the princes of the Tudor line, and was continued and improved upon by the Stuarts. The right was first assumed of remoulding by *governing-charters* the municipal constitution of certain boroughs, which had either ceased to send representatives to parliament or had never exercised that privilege, but upon which this right was now conferred. Most of these charters vested the local government, and sometimes the immediate election of the parliamentary representatives, in small councils, originally nominated by the crown, to be ever after self-elected.

The next step was to claim the same power over municipalities which had always exercised the right of sending representatives. The ignorance or subserviency of the law courts in the reigns of Elizabeth and James I. favoured this design. In the 12th year of the latter monarch, it was judicially declared that the king could by his charter incorporate the people of a town in the form of select classes and commonalties and vest in the whole corporation the right of sending representatives to parliament, at the same time restraining the exercise of that right to these select classes; and such was thenceforward the form of all the corporations which royal charters created or re-modelled.

The perversion of municipal institutions to political ends, the sacrifice of local interests to party purposes, the alienation of corporate property, and other flagrant abuses flowing from the whole powers of the corporations being vested in select bodies, had for more than two centuries been a matter of constant and nearly universal complaint before a remedy was applied by the statute 5 & 6 Will. IV. c. 76, commonly known as "the Municipal Reform Act," but of which the title is, "An Act to provide for the regulation of Municipal Corporations in England and Wales." Upon this Act a number of others have since been grafted, by which various special objects of municipal government are provided for, the whole together constituting a most beneficial code, of which the full results still however remain to be seen. We will endeavour to state succinctly the nature and rules of the existing municipal corporations under the Act 5 & 6 Will. IV. c. 76.

These corporations consist of a mayor, aldermen, and burgesses, by which names they have perpetual succession.

Burgesses.—The qualifications of a burgess, the want of any one of which is fatal to the claim to that appellation, are as follows:—The burgess must be a male, and of full age. He must be found on the last day of August in any year to have occupied a house, warehouse, counting-house, or shop within the borough during that year and the whole of the two preceding years. He must during that period have

been an inhabitant householder within the borough or within seven miles of it. He must be duly enrolled on the burgess-roll for that year; and to be entitled to enrolment, he must have been rated to the relief of the poor during such time of occupancy for his premises within the borough, and must have paid on or before the last day of August in that year all poor rates and all borough rates (if any) payable by him in respect of such premises, except such as become payable within six calendar months before the said last day of August. He need not during the period in question have continued to occupy the same premises. Disqualifications are, being an alien, having been convicted of bribery, and having within twelve months next before the said last day of August received any parochial relief, alms, or charitable allowance.

It is the duty of the overseers of the poor to prepare a list of the burgesses every year, which is to be delivered on the 1st of September (20 & 21 Vict. c. 50, s. 7) to the town clerk, who causes copies to be printed and sold, and fixes a copy on the door of the town hall from the 8th to the 15th of September. This affords an opportunity for all persons who claim to be inserted in the burgess-lists, if they find their names omitted, to assert their rights, which must be done by giving notice of their claim to the town clerk on or before the 15th of September. In the same way, objections may be raised to names supposed to be improperly inserted. Lists of the claims and objections made are framed by the town clerk and fixed up on the door of the town hall from the 23rd of September to the 1st of October. A court for the revision of the burgess-lists is held by the mayor and two borough assessors between the 1st and the 15th of October. The claims and objections are heard, and upon the evidence given the mayor inserts the names of those who establish their claim, and expunges the names of those against whom an objection is successfully maintained. Any other mistake, as the insertion of the name of a dead person, may also on this occasion be corrected. The mayor's decision as to the rejection of any name from the burgess-list is under the control of the Queen's Bench; and under 7 Will. IV. & 1 Vict. c. 78, persons whose claims have been rejected, or whose names have been expunged, may apply for a mandamus to have their names placed on the burgess-roll.

The burgess-lists, when revised, are reduced by the town clerk into alphabetical order, and entered in a book, each name being numbered. This book is the *Burgess-roll*; it must be completed on or before the 22nd of October, and every person whose name is found in this roll is entitled to vote at elections of councillors, assessors, and auditors of the borough from the following 1st of November until the 1st of November in the succeeding year.

Councillors.—On the 1st day of November in every year (or if it be Sunday, then on the following day) an election of councillors takes place. The number of councillors is various in different towns. When a town is divided into wards, each ward elects its own councillors. The qualifications for the office are these:—The candidate must be on the burgess-roll for the current year; and, in case the borough be divided into four or more wards, he must be possessed of property to the amount of 1000*l.*, or rated to the poor of the borough upon an annual value of not less than 30*l.* If the borough be divided into less than four wards, it is sufficient if he be worth 500*l.*, or rated to the poor upon an annual value of not less than 15*l.* No person in holy orders nor regular dissenting minister can be elected, nor any one holding any office in the gift of the council, except that of mayor; nor one having any interest in any contract or employment with, by, or on behalf of the council. Conviction of bribery at a municipal election also constitutes a disqualification. The recorder of the borough is prohibited from being a member of the council. One-third of the whole number of councillors go out of office every year, according to seniority of election, so that the office is held by each councillor for three years.

Aldermen.—The number of aldermen is one-third of the number of councillors. One half of the whole number of aldermen go out of office every third year, being those aldermen who have held the office for the longest time without re-election. The places of the outgoing aldermen are supplied by the council, who, on the 9th day of November, elect the necessary number of persons from the council or from amongst the burgesses who are qualified to be councillors. An outgoing alderman may be re-elected. Every alderman may be called upon once in three years, upon the requisition of any two members of the council, to make and subscribe a declaration that he is qualified to the same amount in real or personal estate, or both, as the amount mentioned in the declaration originally made by him.

In case of the death of the mayor, or his incapacity to attend to his duties, one of the aldermen may be temporarily chosen by the council to supply his place. Aldermen are also chosen by the councillors in each ward to preside at ward elections. Every alderman is a member of the council during his tenure of office. In other respects the functions of the alderman do not differ materially from those of the councillor.

The Mayor.—The mayor is elected on the 9th day of November in every year, by the council, out of their own body, consisting, as we have seen, of aldermen and councillors. The outgoing mayor may be re-elected. In case of a vacancy occurring during the year, a new mayor must within ten days be elected, who holds office for the

remainder of the current year. The council may award the mayor an allowance or salary. The mayor takes precedence in all places within the borough, and during his year of office and the succeeding year is a justice of the peace. He presides at all meetings of the council, and may call meetings as often as he pleases. He may appoint an alderman or councillor to act as his deputy during his illness or absence, which deputy, however, cannot *ex officio* act as a justice of the peace, nor preside at any meeting of the council unless appointed by the meeting to do so.

Auditors.—Two auditors for the borough are elected by the burgesses on the 1st of March in each year. The mayor also nominates one auditor on the same day. The elective auditors are elected from persons qualified to be councillors; the mayor's auditor must be a member of the council. The duties of these officers are to examine and audit the borough accounts half-yearly.

Assessors.—Two assessors for the borough are elected by the burgesses on the 1st of March in every year, whose duty it is to assist the mayor in the revision of the burgess-lists. If the town be divided into wards, two assessors are also annually elected for each to preside with the alderman of the ward at ward elections.

Town Clerk.—This important officer is appointed by the council, and holds his office during pleasure. The council may award him a salary; and he must not be a member of the council. He may be, and in fact usually is, an attorney. All the charters, deeds, muniments, and records of the borough, or relating to the property thereof, are placed in his charge and custody, under the control and direction of the council.

Treasurer.—This officer is also appointed by the council, and holds office during pleasure. He may receive a salary, and must not be a member of the council. The offices of town clerk and treasurer cannot be united in one person. The treasurer keeps the borough accounts, and makes and receives all payments from or to the borough fund.

Other Officers.—The council also appoints a clerk of the peace, and a borough coroner in boroughs having a separate court of quarter sessions; and they may also appoint such other officers as have been usually appointed in the borough, or as they shall think necessary. The offices of recorder, borough justices, and police magistrates, when such are required, are in the appointment of the crown.

Declarations and Oaths.—Under the statute 9 Geo. IV., c. 17, every person elected to the office of mayor, alderman, town clerk, or common councilman, or to any office of magistracy, or place of trust or employment relating to the government of any city, corporation, borough, or cinque port within England and Wales or Berwick-upon-Tweed, must, one calendar month before or upon his admission to office, make and subscribe this declaration:—

"I, A. B., do solemnly and sincerely, in the presence of God, profess, testify, and declare, upon the true faith of a Christian, that I will never exercise any power, authority, or influence which I may possess by virtue of the office of ——— to injure or weaken the Protestant Church as it is by law established in England, or to disturb the said Church, or the bishops and clergy of the said Church, in the possession of any rights or privileges to which such Church, or the said bishops and clergy, are or may by law be entitled."

The statutes 1 & 2 Vict. c. 5, 1 & 2 Vict. c. 15, and 8 & 9 Vict. c. 52, by a slight alteration of this declaration (omitting the words "upon the true faith of a Christian"), have adapted it to the scruples or religious differences of Quakers, Moravians, Separatists, and Jews, so that members of all these persuasions can be elected to municipal offices in common with their fellow-citizens.

No person elected mayor, alderman, councillor, auditor, or assessor for a borough can act as such without first making a declaration before two or more aldermen or councillors, to the effect that he will faithfully fulfil the duties of his office according to the best of his judgment and ability, and that he is possessed of the amount of property required as a qualification, over and above what will satisfy all his debts. A person duly elected to the office of mayor, alderman, councillor, auditor, or assessor, is bound either to accept office or to pay a fine to the borough, not exceeding 100*l.* in the case of mayor and 50*l.* in that of the other offices mentioned, as the council by bye-law shall declare. Lunacy, imbecility, deafness, blindness, or other permanent infirmities of body are valid grounds for exemption from serving and from the fine. Military, marine, and naval officers of her Majesty on full pay are also exempt, and any person above the age of 65 years, or who has already served or paid a fine for non-acceptance of office within five years from the time of re-election, may claim exemption, provided they make their claim within five days after receiving notice of their election.

Functions and Duties.—All acts of the corporate body are ratified by the annexation of the common seal, which expresses the assent of the whole body. The council, consisting of the mayor, aldermen, and councillors, is the acting organ of the general body, and the business of the borough is transacted at its meetings, general and special. Under the Municipal Corporation Act, three clear days' notice of every meeting, signed by the mayor, must be fixed on or near the door of the town hall. In case of the death, resignation, or removal of the mayor, the town clerk must sign the notice of the meeting to be convened in order to fill the vacant place of mayor. Quarterly meetings for the transaction of general business are appointed to be held, one at noon on the 9th of November (or the next day if that be Sunday), and the other three upon such days as the council shall at that meeting

appoint. No notice of the business to be transacted at these quarterly meetings need be given.

The mayor may call a special meeting as often as he thinks proper. Should the mayor refuse to call a meeting, when requested so to do by writing signed by five members of the council, those five members may call a meeting, of which they must give due notice, and which they must sign, stating at the same time the business to be transacted. A summons to attend, specifying the business to be transacted, signed by the town clerk, must be left at the abode of every member of the council three clear days before every special meeting; and no business save that specified in the summons can be transacted at the meeting. At every meeting the majority of members present decides all questions, provided the whole number present be not less than one-third of the whole council. The mayor, or in his absence such alderman, or if no alderman be present such councillor, as the rest shall choose for chairman, presides, and in case of equality of votes has a casting vote. Minutes of the proceedings are drawn up and entered fairly in the minute-book, and must be signed by the chairman at the meeting. These minutes are open to the inspection of any burgess at all reasonable times on payment of a fee of one shilling.

The council may appoint out of their own body committees for general and special purposes, whenever it is thought that the matter in question can be better managed by means of a committee. The acts of all committees must be submitted to the council for approval.

The council may make bye-laws for the good rule and government of the borough, and for prevention and suppression of such nuisances as are not already punishable in a summary manner by virtue of any Act in force throughout the borough, and may appoint such fines, not exceeding 5*l.*, as they may deem necessary to enforce the observance of these regulations. Such bye-laws, however, have no force until the expiration of forty days after a copy sealed with the common seal has been sent to one of the secretaries of state, and has been affixed to the door of the town hall or some other public place within the borough, and such bye-laws may be annulled or modified by the crown with advice of the privy council.

Police.—It is the duty of the council to appoint out of their own body a committee entitled "The Watch Committee," for managing affairs of police within the borough. This committee appoints constables, who may act within seven miles of the borough, and who are empowered to apprehend idle and disorderly persons disturbing the public peace, or whom they may reasonably suspect to intend felony, and to deliver such to the constable in attendance at the nearest watch-house. The watch committee must transmit a quarterly report on the 1st of January, 1st of April, 1st of July, and 1st of October, to the secretary of state, with a copy of their rules for the management of constables.

Paving, Lighting, &c.—By the Municipal Corporation Act, and by 6 & 7 Will. IV. c. 105, and 20 & 21 Vict. c. 50, provision is made for the transfer to the body corporate of the borough of the powers for paving, lighting, supplying water, and other useful objects, which under a multitude of local acts had been previously vested in the old corporations or in separate bodies of trustees. Charitable trusts, of which the old corporations were the depositaries, are not transferred to the councils, but have been confided to distinct bodies of trustees.

Borough Fund.—The rents and profits of all hereditaments, and proceeds of all personal property, dues, fines and penalties, and moneys arising from the sale of copies of the burgess-roll, overseers' lists, and lists of claims and objections, are directed to be paid to the treasurer of the borough, and constitute the borough fund. The council are restrained from alienating or mortgaging lands or granting leases (except leases not exceeding 31 years without fine), unless with the consent of three lords of the treasury. An exception is made, however, with regard to certain leases renewable by custom, and building leases.

The purposes to which the borough fund is applicable are, the payment of the salaries of the mayor and other officers, all the expenses attending the preparation of the burgess-list and municipal elections, the expenses of the prosecution and punishment of offenders, the maintenance of the borough jail and other public buildings, and various other municipal expenses. Certain contributions are also required to be made to the county treasurer for public purposes; and other expenses to be presently referred to, have been charged by sundry Acts of Parliament upon the borough fund.

If the borough fund be more than sufficient for all the purposes defined by law, then the surplus is to be applied, under the direction of the council, for the public benefit of the inhabitants and the improvement of the borough. Should the borough fund be insufficient for the above-mentioned purposes, the council are empowered to levy borough rates for the purpose of supplying the deficiency.

The treasurer keeps accounts of receipts and disbursements, and the account books are open to the inspection of any alderman or councillor. They are audited half-yearly, in the months of March and September, and after the September audit a full abstract is printed and published. A full statement of accounts is sent to the secretary of state before the 1st of March in every year.

Justice.—With regard to the administration of justice in boroughs under the Municipal Corporation Act, the crown is empowered to appoint, in the boroughs named in schedules A and B of that Act,

justices of the peace, who are not required to have any qualification of estate. The council also of every borough may, if they think it necessary that one or more salaried police magistrates should be appointed, make a bye-law fixing the amount of salary, and thereupon the crown may appoint a barrister of five years' standing to the office. The appointment is vested in the crown, in order that the administration of justice may be above the suspicion of being tainted by party or local interests, which might be incurred if the appointment was made by the town council. In boroughs where the council signify their desire to that effect by petition, setting forth the grounds of their application, the state of the jail, and the salary which they are willing to pay, the crown may appoint a recorder for any one such borough, or for two or more conjointly. He must be a barrister of not less than five years' standing.

Prisons.—In every borough to which a separate court of sessions of the peace is granted, there must be one common jail, and at least one house of correction, excepting where the corporation contract for the maintenance of borough offenders in some county or borough jail, or house of correction, or in some district prison. The regulation of the jail is entrusted to the borough justices, for which purpose they hold a quarterly session at the usual times of holding quarterly sessions of the peace.

Lunatic Asylums.—The Lunatic Asylums Act, 1853, directs that in every borough having a quarter sessions, recorder, and clerk of the peace, or having had at the passing of a previous Act (8 & 9 Vict. c. 126, 8th Aug., 1845) six justices or more, besides a recorder, a pauper lunatic asylum be provided or hired. The justices of the borough may contract with the justices of any other counties, boroughs, or hospitals, for the reception of the borough lunatics, or they may contract for the erection and provision of a joint lunatic asylum, for the reception of lunatics of other places, as well as their own borough. The charges of the asylum are thrown upon the borough fund, or, if necessary, upon a general borough rate levied for the express purpose.

Public Libraries and Museums.—The Public Libraries Act, 1850, authorises the mayor, upon the request of the town council of any municipal borough, the population of which at the last census exceeded 10,000, to take the sense of the community as to the desirability of putting this Act into operation. A poll of the burgesses is held after a ten days' notice, and if two-thirds of the votes are in its favour the Act is adopted. The Act enables the council to purchase or hire the necessary lands and buildings, and to erect and maintain necessary buildings, and for this purpose to levy a rate, which must not exceed in any one year one halfpenny in the pound on the annual value of the property in the borough rateable to the borough rate.

The council, and committees appointed by them, are authorised to make rates for the conduct of the museum and library, and the appointment and salaries of officers. Admission to such libraries and museums is to be free of all charge. The council may, with the approbation of the Treasury, borrow money on security of the rate levied under this Act.

Public Baths and Wash-houses.—The 9 & 10 Vict. c. 74 (1846), which is intended to encourage the establishment of public baths, wash-houses, and open bathing-places, may be adopted by the council of an incorporated borough, and may then be carried into operation in accordance with the existing laws and regulations relating to the borough. The expenses may be charged upon the borough fund or supplied by a separate rate. The council have the control and regulation of the baths and wash-houses thus established. They are also empowered to raise money for the purposes of the Act upon security of the borough fund.

Public Health Act, 1848.—This important Act, which is directed to the promotion of the health of towns and populous places, by the supply of water, and the improvement of the sewerage and draining, may be brought into operation in boroughs upon the petition of not less than one-tenth of the inhabitants rated to the poor, or without this in places where it can be shown from the registrar-general's return that the annual number of deaths exceeds 23 in 1000. A report having been made to her Majesty by the General Board of Health upon the case, the Act is put in force by an order in council. But in cases where a local Act of Parliament for cleansing, water supply, &c., is in force, the order in council must be ratified by Act of Parliament before it takes effect. In districts consisting solely of a corporate borough, the council of the borough are constituted the local board of health; in larger districts, including more than a borough, the mayor and a portion of the councillors are to be members of the local board of health formed for the united district.

Nuisances Removal and Diseases Prevention Act, 1848.—In places where the Public Health Act is not in force, the council of the borough may, upon the receipt of a notice signed by two inhabitant householders of the existence in any house or premises of a privy, cess-pool, or other nuisance dangerous to health, cause the premises to be examined; and if satisfied of the dangerous nature of the nuisance, either by such examination or the certificate of two medical practitioners, the council may lodge a complaint with a justice, who may summon the owner to appear, and order the nuisance to be removed within two days. In default of this being done by the owner, the council may themselves

cause the nuisance to be removed, and recover the costs against the owner or occupier.

Public Buildings, &c.—Powers of building, enlarging, or repairing town halls or council houses, police offices, borough jails, or houses of correction, are imparted to the councils of boroughs by the Acts 7 Will. IV. & 1 Vict. c. 78, and 5 & 6 Vict. c. 53 & c. 98. They are empowered to borrow money and to purchase land for such purposes. Bridges within the limits of the borough, and which are repaired at its expense, are placed under the management of the council.

The number of Acts affecting more or less directly municipal corporations in England and Wales, commencing with the Municipal Reform Act (5 & 6 Will. IV. c. 76) up to the present time is not less than sixty; and the reader must be referred to special treatises upon the subject for more minute information. (See Blackst., 'Comm., vol. i., p. 515, Mr. Kerr's ed.; Rawlinson's 'Municipal Corporation Act'; Merrifield's 'Burgesses' Manual'.)

In Ireland the municipal system was amended by the Act 3 & 4 Vict. c. 108 (1840), the provisions of which resemble in many respects those of the English Municipal Reform Act. In Scotland, by the Acts 3 & 4 Will. IV. cc. 76 & 77, the constitution of the common councils in such burghs as had formerly possessed bodies of this kind was reformed, and councils were conferred upon such burghs as had previously had none.

MUNICIPIUM, a term which properly denotes, according to its etymology (*mumus* and *cipio*), the capacity of enjoying rights with the liability to duties. It is however used in the ancient Roman writers to express a class or body, the members of which are called *Municipes*.

Municipium, as a collective name for a number of individuals, had different significations at different periods of Roman history. In its oldest sense, it signified those inhabitants of Italian towns which had a league or treaty with the Roman state, by which the citizens of such towns, though not Roman citizens, enjoyed, when at Rome, all the privileges of Roman citizens, except the suffrage and the eligibility to the honours of the state (*magistratus*), and were also subject to the burdens of Roman citizens; the *Fundani*, *Formiani*, *Cumani*, *Acerrani*, *Lanuvini*, and *Tusculani*, are mentioned as examples. A Roman jurist (*Servius*, the son) says that *municipes* originally signified those who became citizens, their own state remaining perfectly distinct from and unconnected with the Roman state, and who were not allowed to attain to the dignities of the Roman state. (*Fest. Epit.*, 'Municipium'.)

A second class of *municipes* is defined to be those whose State had become a part of or was blended with the Roman state, as was the case with the inhabitants of *Caere*, *Aricia*, and *Anagnia*. (*Festus*, 'Municipium'.) But this would appear to be a misapplication or improper application of the term, inasmuch as this class of *municipes* comprehended those who ceased to have a State of their own, but were incorporated with the Roman state on such terms as the latter chose to grant.

A third class is defined (but the definition is somewhat obscure) to comprehend those towns which received the Roman citizenship, and at the same time became *municipia*: *Tiber*, *Præneste*, and other towns are cited as examples. Niebuhr observes that the places mentioned in this third class were either "all Latin colonies or Italian towns, such as by the Julian Law, or by those which followed and gave it a wider application, became *municipia* in the later general sense." It seems to be clear from this definition that *municipium* must here be understood not in the sense which it has in the first definition, but in the later sense of a town called a *municipium*. For the first part of the definition gives to the *municipes* of this class the full Roman citizenship; and the second part adds (what might very well have been understood without the addition) that the towns included in this definition must have had a local administration. These towns in effect became integral parts of the Roman state, having before been separate, and as a necessary consequence their local administration, which must still have subsisted, became subject to the general Roman law, instead of being independent of it. Such towns were the *municipia* of the Imperial period. The definition of *municipes* by *Paulus* is, "those who are natives of the same *municipium*." *Ulpian*, who also (*D.* 50, i. 1.) gives the same definition of *municipes*, refers to the original signification of the term: "*muneris participes recepti in civitatem ut munera nobiscum facerent*." He adds: "but now, by an abuse of the term, *municipes* is the name given to the citizens of any particular town, as for example, a *Campanus* or *Puteolanus*. He who is born of a *Campanian* father and mother is therefore a *Campanian*: if his mother be of *Puteoli*, he is still a *Campanian municipes*, unless by some special privilege (*privilegium*) he is a *municipes* of his mother's city, a favour which is granted to some cities."

It appears then that the *municipium*, as an ancient Roman institution, may be defined generally as the communication of the rights of Roman citizens (and as a consequence, their liabilities) to Italian towns by treaty or agreement. It thus resembles the *isopolity* (*ισοπολιτεία*) of the Greeks. It is easy to conceive that the rights thus conferred might be either the complete rights of Roman citizenship or only part of such rights. After the freedom of the city was extended to all Italy, and subsequently to the provinces, there was no essential difference between a *colonia* and a *municipium*, though the origin of their connection with the Roman state was very different. [*COLONY*.] Thus, under the emperors, all the inhabitants of the same town,

whether it was a *colonia* or a *municipium*, might with propriety be called *municipes*, notwithstanding the criticism of *Gellius* (*xvi.* 13).

Under the emperors we find various towns in the provinces, as in Spain and Britain, which were erected into *municipia*. The members of these towns were Roman citizens, and administered the affairs of their own community, subject to the general laws by which all Roman citizens were bound. A *municipium* had a corporate character, under which all the *municipes*, that is, all the members of the city, were comprehended. It would appear as if the *decuriones* were sometimes considered as the corporate body representing the *municipium*. The *municipium* could sue and be sued, and could acquire and hold property. The *decuriones* were the senate or council of a *municipium*; and the two chief magistrates were called *duumviri*. The *municipia* had also other local magistrates; and many of them had a mint, as we see from their extant coins. Thus the later *municipia* of the empire were in all respects like modern corporate towns, of which they were undoubtedly the origin and the type.

It follows from what has been said, that an Italian town was originally called *municipium*, or the inhabitants *municipes*, solely with reference to the participation of the townsmen in the privileges of Roman citizens, and that under the republic such *municipia* were in all respects independent of Roman law in their internal organisation. The *municipia* included in the third definition, and the later *municipia* erected under the emperors, were improperly so called, inasmuch as the inhabitants of these towns became, or were, Roman citizens, and in all respects subject to Roman law.

The original signification of *municipium* in the old Roman constitution is discussed by Niebuhr ('*Roman Hist.*' vol. ii.) in an instructive chapter, which contains all the necessary references. It is not easy, however, to assent to all this writer's opinions.

For a more extensive inquiry into this subject, the reader may consult *F. Roth*, '*De re municipali Romanorum*'; *Savigny*, '*Gesch. de R. R. im Mittelalter*,' t. i. c. 2; and *Heineccii* '*Antiquitat. Roman. Syntag. App.*' lib. i., cap. v.

MUNIMENTS. This word is a derivation from *munio*, which signifies "I defend," and originally designated those writings in which are recorded the transactions of former times, out of which existing relations, in respect of political rights, social rights, or property, arise. Hence, by showing their origin, they defend the possession of them by those who have rightfully inherited them.

But *muniments* has, in the course of ages, acquired a somewhat different sense; and from betokening the documents themselves, it is sometimes used to denote the *depositories* of these documents.

Still, by those who aim at speaking with precision, it denotes the written documents themselves. It is also rarely used in reference to any small collection of such documents, or when the interest to be defended is small. In such cases the correlative expressions are *title-deeds*, or *evidences*, which means however precisely the same thing, only on a smaller scale. But when we speak of the documents by which the rights of a person are defended in whom a large estate has centred, or who inherits an ancient title, or vast manorial or ecclesiastical privileges, then the word of greater dignity, *muniments*, is often used; and still more when the evidences are spoken of which show the right of the crown of any kingdom to its possessions, or the right of crown or people as sustained by written documents.

Private collections of evidences rarely contain anything that is of earlier date than the reign of *Edward I.* The public muniments of the English nation are believed to excel those of any other nation, both in number, preservation, and the remoteness of the period at which series or classes begin. Yet there is little previous to the reign of *Richard I.* There is no series commencing before that reign, except that of the *Pipe Rolls*, the *Great Roll of the Exchequer*, in which were entered, year by year, the receipts of the crown, and many of its payments. This series begins in the second year of *King Henry II.*, and from that remote period to the year 1835, when this mode of keeping the account ceased, there is scarcely a roll wanting in the whole series. For the time previous to the beginning of that reign, one roll, which belongs to the reign of *Henry I.*, only exists of this series; and the only other record of great importance before the reign of *Henry II.* is that called '*Domesday Book*,' a survey of nearly the whole of the kingdom, made by *William the Conqueror*, a book which is still sometimes appealed to in determining rights of the crown, or of a subject against the crown, or of one subject against another.

For the particular classes of public muniments, their depositories, preservation, and other information concerning them, see **RECORDS**, **PUBLIC**.

MUNTZ METAL. [*BRASS*.]

MURDER. In the earlier periods of English jurisprudence, murder, *murdrum*, was a term used to describe the secret destruction of life, witnessed and known by none besides the slayer and any accomplices that he might have; so that the hue and cry, which the law required to be made after malefactors, could not be raised.

Murdrum was also the name of an amercement or pecuniary penalty imposed, until the reign of *Edward III.*, upon the county or district in which such a secret killing had taken place. One of the modes of escaping from this penalty was, a presentment of *Englishry*; in other words, a finding by the coroner's inquest, upon the statement of the relations of the deceased, that he was an *Englishman*; the sole object

of the amercement having been the protection of Danes, and afterwards of the Normans, from assassination by the English. (Glanville; Reeves.)

By the grant of "murdr," which is commonly found in ancient charters of franchises, the right to receive these amercements within the particular districts, passed from the crown to the grantee. Amercements for non-presentment of Englishry were abolished in 1340, by 14 Edw. III., st. 1, c. 4.

As the law formerly stood, every destruction of human life, not effected in this secret manner, with whatever circumstances of malignity and cruelty it might be accomplished, was treated as simple homicide. The law appears to have been gradually altered by the judges, in order to reach atrocious criminals whose offences would not formerly have been punishable as murder. As the law now stands, murder is the destruction of human life, accompanied with an intention on the part of the perpetrator of the offence to kill or do great bodily harm, or wilfully to place human life in peril; or resulting from an attempt to commit some other felony; or occurring in the course of resistance offered to ministers or officers of justice, or others rightfully engaged in carrying the law into execution. All other cases of culpable homicide, in which death is produced involuntarily, but is occasioned by want of due caution; or where, though death is produced voluntarily, the crime is extenuated by circumstances; or where a minister or officer of justice is killed, but sufficient authority did not exist, or was not communicated to the party before the fatal blow was given; or where any other circumstances essential to the crime of murder are wanting—amount only to simple felonious homicide, or, as it is commonly called, without regard to the age or sex of the party killed, manslaughter.

The law recognises the right of taking away life in the necessary defence of person or property, and it admits, in some cases, previous provocation as an extenuation of the offence. On the other hand, it makes special provision for the protection of officers and ministers of justice, where the killing of such officer or minister, though culpable, does not under the circumstances amount to murder.

In the modern law of England the crime of murder is characterised by having been committed with malice aforethought, or, as it is sometimes called *premeditation*; which term, though in its ordinary signification it imports premeditation, has been extended to cases not only where the offender acts from a motive of ill-will towards another, with an express intention to destroy or injure him, but also where, without the existence of express malice, it is considered necessary, on grounds of policy, to punish homicide with the highest degree of severity.

The term "malice aforethought" is therefore frequently applied to a state of things in which no malice is felt in the ordinary sense of the term, but is only malice in a legal sense, by construction of law.

If A shoots at B with intent to kill him, but by mere accident kills C, this is a killing from implied malice. If A, by throwing a heavy stone from the roof of a house into the street in which he knows that people are continually passing, kills B, a mere stranger, this also is a killing from implied malice.

Implied malice is however very loosely defined in the law of England, if it can be said to be defined at all. It is stated, that the existence of implied malice is a pure question of law, or a conclusion of law to be drawn from all the circumstances of the case; and it is in some cases made to depend upon a very abstruse technical doctrine. The existence or non-existence of a criminal intention, even where that intention has no reference to any personal injury, but happens to be accompanied with a killing which is altogether accidental, is made to constitute the distinction between the higher and lower species of culpable homicide; and in other cases the existence of such criminal intention brings even an accidental killing within the scope of manslaughter.

Mr. Justice Foster says, "When the law maketh use of the term 'malice aforethought,' as descriptive of the crime of murder, it is not to be understood in that narrow restrained sense to which the modern use of the term 'malice' is apt to lead one, a principle of malevolence to particulars; for the law, by the term 'malice' in this instance meaneth, that the fact hath been attended with such circumstances as are the ordinary symptoms of a wicked, depraved, and malignant spirit. The *malus animus*, which is to be collected from all circumstances, and of which the court, and not the jury, is to judge, is what bringeth the offender within the denomination of wilful malicious murder. And I believe most, if not all the cases which in our books are ranged under the head of implied malice, will, if carefully adverted to, be found to turn upon this single point—that the fact hath been attended with such circumstances as carry in them plain indications of a heart regardless of social duty and fatally bent upon mischief." ('Discourse on Homicide,' 256, 257.)

This vague and figurative description of that which is propounded as a legal definition appears to furnish us with no certain test of the crime of murder. It amounts to no more than this: that, to constitute the crime of murder, the act must have been attended with such circumstances as in the opinion of the court, and not of the jury, are "the ordinary symptoms of a wicked, depraved, and malignant spirit," or "a heart regardless of social duty, and fatally bent upon mischief." It is a description of that which is rather matter of fact than of law. The question in each particular case is, whether the party acted in wanton and wicked disregard of the probable consequences of an act tending to the destruction of human life; which is an inference to be

deduced from the evidence; and in arriving at which no assistance can be derived from the application of mere technical rules. The presence of that evil disposition of the mind of the offender which makes the offence murder, is known only by evidence of an act or omission by which human life is wilfully or wantonly exposed to peril.

Every homicide is presumed to be malicious until the contrary be shown. But upon the investigation, circumstances may transpire which extenuate the offence, and reduce it from the crime of murder to that of manslaughter; or the act may appear to amount either to justifiable or excusable homicide. In cases of justifiable homicide, and, according to modern practice, in cases of excusable homicide, the party causing the death is discharged from responsibility.

To constitute legal homicide, the death must result from injury to the person (as contradistinguished from causes operating upon the mind) occasioned by some act done by, or some unlawful omission chargeable upon, the party to whom such homicide is imputed. The terms "wilful omission" apply to every case of noncompliance with a legal obligation which the party may be under, to supply food, clothing, or to furnish any other assistance, or to do any other act, for the support of life or for the prevention of injury to it. It is not homicide unless death take place within a year and a day after the injury; or, in other words, it is not considered homicide when the party injured survives a whole year, exclusive both of the day of the injury and of the day of the death; nor where the death is to be attributed to unskilful treatment, or other causes not resulting from or aggravated by the injury sustained.

The law of homicide applies to the killing of aliens, except alien enemies slain in the heat and in the exercise of war; to felons, except when executed according to law; and to persons outlawed, whether on civil or on criminal process. But a child *in ventris matris* (in its mother's womb) is not a subject of homicide, unless, subsequently to the injury, it be born alive, and die, within a year and a day from its birth, from the injury received whilst yet unborn. [INFANTICIDE.]

Criminal homicide is one of three kinds, murder, manslaughter, and self-murder. [SUICIDE.]

I. Murder is committed by:—

1. Voluntary homicide, without circumstances of justification, excuse, or extenuation.
2. Involuntary homicide, resulting from the commission of a felony, or from an attempt to commit felony.
3. Homicide, whether voluntary or involuntary, committed in unlawfully resisting officers or ministers of the law, or other persons lawfully acting for the advancement or in the execution of the law.

II. Manslaughter consists in:—

1. Voluntary but extenuated homicide, committed in a state of provocation, arising from a sufficient cause.
2. Involuntary homicide, not excused as being occasioned by mere misadventure.

This second class may be subdivided into:—

1. Involuntary homicide, resulting from some act done, or from the wilful omission to do some act, with intent to occasion bodily harm.
2. Involuntary homicide, resulting from some wrongful act done to the person.
3. Involuntary homicide, in committing, or in attempting to commit, an offence attended with risk of injury to the person.
4. Involuntary homicide, resulting from some act done without due caution, or from the unlawful omission to do some act.

Homicide not criminal is:—

1. Justifiable, as done for the advancement or in the execution of the law; or
2. Excusable, as done for the defence of person or property; or because it has, without the fault of the party, become necessary for his preservation.

The offence is extenuated where the act, being done under the influence of excitement from sudden provocation, or of fear, or of alarm, which may, for the time, suspend or weaken the power of judgment and self-control, is attributable to transport of passion or defect of judgment so occasioned, without any deliberate intention to kill or do great bodily harm; regard still being had to the nature and extent of violence used by the party inflicting the injury which causes death, as compared with the cause of provocation. The offence is not extenuated where, the cause of provocation being but slight, a return is made so excessive and disproportionate, that the killing cannot be attributed to mere heat of blood arising from the provocation given.

Homicide is neither justified nor extenuated by reason of any consent given by the party killed, as in cases of duels.

Homicide is justifiable, where the act is done in a lawful manner, by an officer or other person lawfully authorised, in execution of the sentence of a court of competent jurisdiction.

Homicide is justifiable, where an officer of justice, or other person duly authorised to arrest, detain, or imprison for any felony or for any dangerous wound given, and using lawful means for the purpose, cannot, otherwise than by killing, overtake the party in case of flight,

or prevent his escape from justice; provided the officer knew, or had reason to believe, that the party attempting to escape was aware that he was pursued for such felony or wound given.

Also, where any officer of justice, or other person lawfully executing in a lawful manner any civil or criminal process, or other authority for the advancement of the law, or interposing in a lawful manner for the prevention or suppression of any breach of the peace or other offence, is unlawfully and forcibly resisted, and using no more force than is necessary to overcome such resistance, happens to kill the party resisting; or being, by reason of the violence opposed to him, under reasonable fear of death if he proceed to execute his duty, and because he cannot otherwise both execute his duty and preserve his life, kills him who so resists—in either of these cases the homicide is justifiable.

Homicide is also justifiable, when necessary for preventing the perpetration of any felony attempted to be committed by violence or surprise against person, habitation, or property; and where one, in defence of movable property in his lawful possession, using no more force than is necessary for the defence of such property against wrong, happens to kill the assailant; or being, from the violence of the assailant, under a reasonable and *bonâ fide* apprehension that he cannot otherwise both defend his property and preserve his life, kills the assailant; also where one in lawful possession of house or land, after requesting another, who has no right to be there, to depart, is resisted, and using no more force than is necessary to remove such wrong-doer and retain his possession, happens to kill such wrong-doer; or being, from the violence with which such wrong-doer endeavours to deprive him of possession under reasonable and *bonâ fide* apprehension that he cannot otherwise both maintain possession and preserve his life, kills such wrong-doer.

Homicide is excusable, when a man is involuntarily placed in such a situation that he is under the necessity of killing another in order to save his own life; as where, in a shipwreck, A pushes B from a plank which can save one only.

Homicide is, not criminal, when it occurs in the practice of any lawful sport or exercise with weapons not of a deadly nature, and without intent to do bodily harm, and where no unfair advantage is intended or taken. But it amounts to manslaughter where weapons are used, the use of which is attended with probable danger; or where, in friendly contest, without the use of such weapons, death results from any unfair advantage taken, either as regards the nature of the instrument, the mode of using it, the want of due warning given previously to violence used, or from any want of due caution. Tournaments, though a sport in which deadly weapons were used, yet, being considered a useful training to arms, were lawful if held with the consent of the king. In case of death, therefore, in the course of one of these exhibitions, the criminality of the act appears to have depended upon the royal licence for the holding of the tournament. [TOURNAMENT.]

The statute of 9 Geo. IV., c. 31, s. 3, enacts, that every person convicted of murder, or of being accessory before the fact to murder, shall suffer death; and that every accessory after the fact to murder, shall be liable, at the discretion of the court, to be transported for life, or to be imprisoned, with or without hard labour, for any term not exceeding four years. Penal servitude is now substituted for transportation. By an act passed in 1752 (25 Geo. II., cap. 37), the bodies of persons executed for murder were directed to be delivered to surgeons to be dissected, or to be hanged in chains. The 2 & 3 Wm. IV., c. 75, required that such persons should be hung in chains, or buried within the precincts of the prison. The 4 and 5 Wm. IV., c. 26, s. 1, took away the former part of the alternative, and the mode of burial is the only circumstance which distinguishes sentences upon a conviction for murder from those pronounced in other capital cases. Formerly the murder of a bishop, abbot, or prior, by a person owing him canonical obedience, of a master or mistress by a servant, or of a husband by his wife, was denominated petty treason, and punished with greater severity than other murders. The party was drawn to the place of execution; and if the offender was a woman, burning was, as in the case of high treason, substituted for hanging; but by the 9 Geo. IV., c. 31, s. 2, petty treason is to be treated as murder only.

The offence of manslaughter is now punishable with penal servitude for life, or for a term of years, or with imprisonment, with or without hard labour, not exceeding four years, or with fine. (Foster; East; *Fourth Report of Criminal-Law Commissioners.*)

β	5267	4280	4
γ	5184	4224	4
δ	5349	4353	4

MUSCOVADO SUGAR. [SUGAR.]

MUSES (*Musæ*, in Latin; *Μοῦσαι*, in Greek), the name of certain sister goddesses in the Greek mythology, who were supposed to preside over the arts of poetry and music, and the sciences of history and astronomy. The original conception of the Muses must be sought for in that disposition of the human mind which prompts us to embody abstract ideas in a sensuous form. Such seems likewise to have been the origin of the Graces, Fates, Furies, and other mythological personages of that class. [GRACES.] In the instance of the Muses, the powers of memory, music, and song were personified into individual goddesses, who were supposed to inspire men with these gifts. At first the Muses were said to be only three: Mneme, that is, "memory;" Melete, or "meditation;" and Aoide, or "song"; and they resided of old on Mount Helicon in Boeotia. (Pausanias, ix. 29.) According to the poet Alcman, they were the daughters of Uranus and Gæa, or the earth. Cicero ('*De Natur. Deorum*,' iii. 21) mentions four, namely, Thelxinoe, "mind-soother;" Arche, or "beginning;" Aoide; and Melete; and he says that they were the offspring of the second Jupiter. He goes on to say that there were other Muses, nine in number, born of the third Jupiter (the son of Saturn) and of Mnemosyne; and also a third family of Muses, called Pierides by the poets, who were the daughters of the third Jupiter and Antiope, and were similar in their names and equal in number to the preceding. Hesiod, in his '*Theogony*' (53), reckons nine muses, daughters of Zeus and Mnemosyne, and gives their names as follows:—Calliope, Clio, Melpomene, Thalia, Euterpe, Terpsichore, Erato, Polyhymnia, and Urania, and he says that Pieria in Macedonia was their first dwelling-place. These are the Muses generally alluded to by the poets. It appears that the worship of the Muses was introduced from Macedonia into Boeotia, Phocis, and other parts of Hellas. The story of the contest of the Muses with the nine daughters of Pierus, a Macedonian, who pretended to rival the Muses in singing, but were vanquished and changed into magpies (Ovidius, '*Metamorph.*,' v.) may have been, as some critics have conjectured, an allegory originating in the national vanity of the Greeks, to show their superiority in the arts and sciences over their Macedonian neighbours. The Thracian bard Thamyras tried a like chance, with a like result; he had his eyes put out and was deprived of his lyre.

Homer mentions the Muses as the goddesses of song, who inhabited lofty Olympus, but he does not specify their number or names. In the second book of the *Iliad* he invokes them, "to whom all things are known," to assist his memory while he is enumerating the leaders of the Greek forces at Troy. The occupations of the Muses were singing, dancing, and attending the banquets of the Gods. They were the attendants of Apollo and also of Bacchus. The name *Musa* is supposed by some to be derived from a Greek verb which means "to discover," because the Muses were said to be acquainted with recondite mysteries and future events; but this etymology is mere trifling, and the origin of the name is unknown. They were represented as handsome and modest virgins, with an intellectual expression of countenance, and dressed in long tunics, with wreaths of laurel, ivy, or palm leaves on their heads, or occasionally feathers, in allusion to their victory over the Sirens. It was only in later ages that peculiar attributes were given to each of them by the artists, and a peculiar department of science was assigned to each by the poets. In several paintings of Herculaneum they are represented with their respective attributes, and with their respective names written under each. By comparing these with several reliefs, medals, and mosaics, their identity becomes confirmed. The following is a list of the Muses, with the allegorical meaning of their names, and the attributes commonly borne by them:—

Clio, from *cleio*, "to celebrate glorious deeds," is represented with a scroll in her hand, and also sometimes with a "scrinium" to keep MSS. in, by her side; and is commonly seated. She has been styled the Muse of History.

Calliope, "fine voice," is represented with tablets and a style; sometimes with a trumpet in her hand; in some instances, as at Herculaneum, with a scroll like Clio. She was the Epic Muse.

Melpomene, "the singer," wears a royal diadem round her head, and a wreath of vine leaves, with cothurni on her feet; she so stands as to exhibit her full size, and holds a mask in the left hand, and a club in the right. She was the Muse of Tragedy.

Thalia, "the joyous," the Muse of Comedy, is also crowned with vine leaves, has a crook in one hand and a grotesque mask in the other.

Euterpe, "the pleasing," carries a double flute. She presided over music and lyric poetry.

Terpsichore, "dance-loving," carried a lyre and plectrum, and presided over choral poetry and dance.

Erato, "the lovely," carries also a lyre. She was the Muse of elegy and amatory song.

Polymnia or Polyhymnia, "of many songs," is represented wrapped up in her cloak, and buried in meditation, usually leaning her elbow on a rock, sometimes with the fore-finger of her right hand across her mouth, in token of reserve and caution. She was the Muse of religious song, allegories, and mythical strains.

Urania, "the heavenly," has the globe and compasses in her hands, which are the emblems of her calling, astronomy.

In the Græco-Roman rooms in the British Museum, are several statues of different Muses; and the whole of them are twice repre-

sented in bassi-rilievi: on the front of a sarcophagus of later Roman date; and in the beautiful relief known as "Apotheosis of Homer," of the upper portions of which, containing the Muses, we give a cut. In

this the Muses occur in the following order: commencing on the left of the upper line (below the figure of Zeus) we have—Calliope, with her tablets; Clio; Thalia; Euterpe, holding out the double flute;

[The Muses, from a basso-rilievo in the British Museum.]

Melpomene, standing on a rock and addressing Zeus; next her, on the extreme right, is Erato (though some German archaeologists take it to be Thalia, and that just noticed as Thalia to be Erato—the lyre is, however, the usual attribute of Erato); the first figure on the left in the lower row is Terpsichore; the next, Urania; the next, Polyhymnia. The figure more to the right is Apollo Musagetes, in female attire, within the Corycian cave, having a plectrum in his right hand, the lyre in his left, and at his feet the Delphic cortina, or tripod cover, bow, and quiver; the Pythian by his side is offering a libation in a patera.

The corruption which, in the course of ages, pervaded mythological symbols, did not spare the Muses, and accordingly we find their chastity denied by several writers. According to Apollodorus, Ovid, and others, Clio had Orpheus by Apollo, Euterpe had Rhœsus by the Strymon, Calliope was the mother of the Sirens by Achelous, &c.

The favourite haunts of the Muses were, Mount Parnassus in Phocis, Helicon in Bœotia, Pierius, Pindus, and Olympus, in Thessaly, &c. The swan, the nightingale, and the grasshopper were sacred to them. The Roman poets called the Muses Camenæ, an Etruscan name—for it appears that the Etruscans had also their Muses (Micali) and also Pierides.

A magnificent festival called *Museia* (*Μουσεία*) was held in honour of the Muses at Thespiæ in Bœotia, every fifty years.

(Creutzer, *Symbolik und Mythologie*; Petersen, *De Musarum Origine*, in Münter's *Miscellanea Hafniensia*; Hermannus, *De Musis fluvialibus*; Müller, *Handbuch der Archäologie*, § 393, and *Denkmäler der Alten Kunst*, &c., taf. lviii. lix., 732–750; Millin, *Galérie Mythologique*; Keightley's *Mythology of Ancient Greece and Italy*.)

MUSEUM, a place dedicated to the Muses, from the Greek *Mouseion* (*Μουσείον*); hence any place where learning is pursued, or which is set apart as a repository for things that have some immediate relation to the arts, is so termed. The earliest institution we are acquainted with which received this appellation was the museum founded about B.C. 280, at Alexandria by Ptolemy Philadelphus, for the encourage-

ment of learning and the support of learned men. The buildings of this institution were afterwards enlarged by the emperor Claudius. (Suet., 'Claud.,' 42.)

MUSEUM OF PRACTICAL GEOLOGY. [SCIENCE AND ART, DEPARTMENT OF.]

MUSIC (*Musique*, Fr.; *Musica*, Lat.; *Μουσική*, Gr., from *μουσα* a muse or song) is the artistic union of inarticulate sounds and rhythm, exciting agreeable sensations, and raising mental images and emotions directly or indirectly pleasing. Such is pure unmixed music. When conjoined to poetry, it is an art not of diminished importance, but of a dependent nature, its office then being to enforce the meaning of the words and add a colouring to them. As an adjunct it is a beautiful illustration of language; combined with the sister art, it becomes a highly ornamented kind of eloquence.

Music is a kind of language, and as such, says Metastasio, it possesses that advantage over poetry which a universal language has over a particular one; for this last speaks only to its own age and country; the other speaks to all ages and countries. Music is a language that speaks by imitating, and as such it is understood by those who have successfully studied the art, and likewise by mere amateurs, who, with little if any knowledge of its principles, have learnt the meaning of its expressions by long practice, by frequently hearing and enjoying its performance; but it can only express passion and sentiment very generally, and commonly fails when it attempts to particularise. This want of absolute decision in what is called musical language is by some writers reckoned among its advantages, because it gives the hearer great latitude in interpreting it, which he usually does in a manner as congenial as possible to his own feelings at the time.

A musical sound—which is a curious compound of other sounds, called harmonics, resulting from a number of vibrations in equal times—when produced by a fine voice, a rich-toned violoncello, or a "mellow horn," excites in all who possess a moderate share of nervous sensibility

a pleasurable sensation; and this, Sir John Herschel observes, "is perhaps the only instance of a sensation for whose pleasing impression a distinct and intelligible reason can be assigned."

Dr. Beattie does not think it absurd to suppose that the body may be mechanically affected by sound. "If," he says, "in a church one feels the floor and the pew tremble, to certain tones of the organ; if one string vibrates of its own accord when another is sounded near it, of equal length, tension, and thickness; if a person speaks loud in the neighbourhood of a harpsichord, and often hears the strings of the instrument murmur in the same tone, we need not wonder that some of the finer fibres of the human frame should be put in a tremulous motion when they happen to be in unison with any notes proceeding from external objects."

The surprising connection between form and vibrations producing musical sounds, so beautifully shown in Chladni's experiments on plates of glass strewed with sand, and put into sonorous vibration, thereby throwing the sand into various symmetrical figures, may be here incidentally mentioned. Though it does not seem to shed any new light on the subject before us, nevertheless, by proving something like sympathy, and of a much more extraordinary kind than that between two strings, in mere matter, it may at a future period lead to interesting discoveries.

The effect of rhythm, or measure, is universally felt and admitted: the most polished inhabitants of Europe, and the most barbarous natives of the arctic regions, are alive to its influence; it is that which reduces unmeaning sounds to order, converts them into melody, and bestows on them proportion and a power to charm. The chirping, or whistling, or singing, as it is called, of most birds, being devoid of rhythm, affords no pleasure but what is derived from association; while the single note of a drum, beaten in time, combining sound and measure, is gratifying in a certain degree to every hearer. Indeed, with the ancients rhythm was of paramount importance, if not almost everything, in what they denominated music, a term under which was included much that it does not imply in modern language. Aristides Quintilianus, the best of the seven Greek writers on music collected by Meibomius, remarks that rhythm is the object of three senses, namely, the sight, as in dancing; the hearing, as in music; and the touch, as in the pulsations of the arteries.

Much of the effect of music on the mind is ascribed to imitation, which is either direct or indirect. And it must be understood that we are still speaking of music strictly instrumental, not vocal. The power of direct imitation is confined within narrow limits, though composers have often attempted to enlarge the boundaries at the risk of exposing their own weakness and that of their art. The song of some birds, the whistling of winds, the roaring of the tempest, the sound of cannon, the ringing and tolling of bells, and the tones of the human voice expressive of certain emotions, are considered as legitimate objects of direct imitation; but it has been affirmed that the rattling of hail, the fall of snow, the motions of animals, actions at sea, battles on land, &c., are not only unrepresentable by any kind of musical instrument at present known, but unfit for imitation if instruments could be constructed for the express purpose. Of all the powers of music, in the opinion of a good critic, the Rev. Thos. Twining, that of the raising of ideas by direct resemblance is the weakest and least important. "It is indeed so far from being essential to the pleasure of the art, that unless used with great caution, judgment, and delicacy, it will destroy the pleasure by becoming offensive or ridiculous. The highest power of music, and that from which it derives its greatest efficacy, is undoubtedly its power of raising emotions."

Indirect Imitation is that by which some quality common to music and the thing imitated is indicated by sounds, strong or weak, quick or slow. Rage is loud, anger is harsh, love and pity are gentle; therefore loud and harsh sounds raise ideas of the former passions and others of the same class; soft and tranquil sounds raise ideas of the latter and others of a similar character. Hence it will be seen, as before observed, that the hearer may interpret music in a manner corresponding in some degree to the state of mind in which it shall find him, but under certain restrictions from which he cannot be released. If agitated by any turbulent passion, he will find it impossible to convert smooth and delicate music into a language in unison with his irritated feelings; and if under the softening influence of some tender attachment, or of sorrow for the loss of one beloved or valued, he will be unable to construe bold and brilliant sounds as expressions of sympathy. But music that is not of a decided character will prove more or less convertible.

Association, which has so large a share in the operations of the human mind, often contributes much to the effect of music. Indeed some airs, possessing no intrinsic merit, owe their influence solely to this principle and among these the famous *Rans des Vaches*, which, in times happily gone by, acted with such irresistible force on the expatriated Swiss soldier. It was many years after the battle of Culloden, and not till all fears of the Pretender had subsided, that the Scotch bagpipers ventured to play any of the Jacobite tunes, which, when revived, were heard with delight, though hardly one of them would have continued to be listened to but as connected with the history of the country.

After all, however, that has been written and said, from the days of Aristotle down to the present period, of music as an imitative art, it must be conceded that modulated sounds please, by some mysterious

means, many to whom they present no imitation of anything, material or immaterial, and who associate with them no other idea than that of melody or of harmony.

Thus far our attention has been directed to instrumental music, or that which is dependent on no auxiliary for effect, on no words to explain its meaning, on no gesticulation or scenery to illustrate it. We have now to consider music as produced by the human voice in alliance with language, whether poetical or prose, and with or without instrumental accompaniment.

Vocal music is entirely devoid of that ambiguity which some think a merit in instrumental music, and some consider a defect. Words fix the intention of musical sounds, leaving nothing for the hearer to conjecture; for though the more or less of truth in the expression will depend on the skill of the composer, yet he must be utterly destitute of reason to give to revenge the tones of love, or to joy those of despair. It is true that he does not always read with discriminating judgment the words selected by him, or committed to his charge—that in emphasis he is sometimes erroneous, and in accentuation frequently faulty; and for these failings in the artist, the art itself has been unjustly condemned by writers whose repute gives weight to their censure. But the heaviest charge brought against composers of vocal music, and that which has exposed them to the keenest ridicule, is their eagerness to express the literal meaning of a particular word rather than the sentiment, the sense of the entire passage. This exceedingly vulgar kind of imitation, which has not inaptly been called *musical punning*, may be traced to a gross misapprehension of the rule, that "the sound should seem an echo to the sense," and is the vice not only of composers of an inferior order, but occasionally of some of the highest class. The great Handel himself is not wholly exempt from its influence. In the fine chorus, "Wretched lovers, quit your dream" (in 'Acis and Galatea'), when the line "Hark! how the thund'ring giant roars" occurs, he makes the bases roar in a long division, till they nearly gasp for breath. But this is a verb that proves very seductive to composers; in two of our best glees it sets the voice a-roaring through several bars:—in the one, because the poet (Ossian) asks, "Who comes so dark from ocean's roar?" In the other, because the poet (Gray) says, "The rocks and nodding groves re-bellow to the roar!" Handel's favourite air, "What passion cannot music raise and quell?" from Dryden's 'Ode to St. Cecilia's Day,' sends the voice tumbling down a full octave at the words "faces fell." In the same work the singer is condemned to ascend to a note which few can reach, and none can sustain without lungs of very unusual capacity, merely because the author says, "The trumpet shall be raised on high." Our greatest English composer, Purcell, could not resist the temptation offered by the words "They that go down to the sea in ships," from the 107th Psalm, in setting which he commits the bass voice to so very low a deep, that there was only one man in his day who could sing the anthem. "Some eminent musicians," Sir William Jones observes, "have been absurd enough to think of imitating laughter and other noises; but if they had succeeded, they would not have made amends for their want of taste in attempting it; for such ridiculous imitations must necessarily destroy the spirit and dignity of the finest poems." This discerning and elegant writer most likely points at the song and chorus, "Haste thee, nymph," in Handel's setting of Milton's 'L'Allegro,' in which is the line, "And Laughter holding both his sides." The singers in this, it must be allowed, never baulk the intention of the composer, but affect to laugh almost convulsively. Many other instances of similar mistaken efforts at direct imitation might be adduced from the works of Handel, and that great composer's supremacy in the art renders him especially liable to animadversion when misled by an erroneous conception of the words; but he has been charged with many supposed imitations which he never contemplated, such as the *whipping-chorus*, the *rocking-chorus*, &c. We have however said as much as is necessary on this part of our subject.

In the accompaniment to vocal music, much greater freedom of imitation is allowable than in the voice part: kept within those bounds which good sense and cultivated taste prescribe, it affords very efficient aid, by giving greater force to the poetry, and contributing to the completion of the general design. It also adds harmony to song, a most important, if not an indispensable support. Nearly all that imitation can do, should—as the elder Dr. Gregory, of Edinburgh, in some admirable remarks on music, has observed—be assigned to the accompaniments, as these, on account of the greater compass and variety of instruments, are better adapted to such a purpose than the voice, which ought to be left at liberty to express the sentiments. If Handel has sometimes failed in imitations by the voice, he has often succeeded in those by the accompanying instruments. We need but refer in proof to his beautiful song in 'Il Penseroso'—

"Oft on a plot of rising ground
I hear the far-off curfew sound,"—

where he has imitated the bell by the deep-toned strings of the bases, confining the voice to those notes of pleasing, contemplative melancholy, the idea of which the words so completely excite. The same skill and discrimination are shown in the song of Galatea, "Hush! ye pretty warbling quire," in which the flute imitates the birds, leaving the singer to express in simple sounds that languishing tenderness

indicated by the poetry. Handel was the first who endeavoured to excite the idea of light through the agency of musical sounds: his chorus in the oratorio of 'Samson,' "O first created beam!" was written with this design; and moreover suggested to Haydn that grand composition on the same subject which is admitted to be one of his noblest triumphs. But the still bolder attempt of the former great master was to convey to the mind, through the same medium, a notion of darkness. With this view he composed the sublime chorus in 'Israel in Egypt,' beginning, "He sent a thick darkness over all the land," the accompaniments to which, assisted by the words, produce on persons susceptible of musical impressions all that solemnity of effect, not unmixed with awe, intended by the author. The same may be said of the remaining plagues, in which the instrumental is the imitative and suggestive portion of the music, while the vocal portion is frequently but a simple plaintive air. The accompaniment to the words "There came all manner of flies," is wonderfully expressive of myriads of flitting, buzzing, fluttering, humming insects in motion; and the description of the entrance of the frogs even into the king's chamber, is rendered vivid by the measured leap performed by hundreds of instruments, and that without the slightest approach to the ludicrous. That grand chorus which announces the congealing of the waters, is mainly indebted for the extraordinary sensations which it produces to the marvellous accompaniments, which seem to betoken a solidifying stiffening process, gradually extending over the whole orchestra and over the listeners. Some of the grandeur of these effects is due to the greatly increased orchestras of the present day, which go far to realise the composer's original idea. A full orchestra in former days contained perhaps 100 performers, whereas at the present time 1500 skilled musicians may take part in these choruses.

Haydn, though sometimes ambitious of achieving by musical means more than the art can accomplish, was often most happy in indirect imitation by instrumental accompaniments; witness the magnificent burst of sound in the first chorus—to which we have just alluded—in 'The Creation,' at the words, "and there was light." Witness also his musical picture, in the same oratorio, of the rising sun, the slow swell of the instruments in ascending notes describing the gradual progress of the luminary towards the horizon, and the full power of the band depicting its refulgent splendour. And how beautifully the composer contrasts with the solar blaze, the soft, serene beams of the comparatively small orb which reflects its borrowed light!

Music, which is both a science and an art, is divided into *Speculative* or theoretical, and *Practical*. Speculative Music explains the nature of musical sounds; shows, by demonstrating their ratios, how they are related to each other; and investigates their physical and moral effects when in a simple or in a combined state: it is, in few words, the philosophy of the art. Practical Music is the application of theoretical principles,—the proper conduct of sounds as to their progression, duration, union, and adaptation to words, voices, and instrument, and is the art of composition. The performer, who merely executes, stands in the same relation to music as the actor does to the drama, or the reciter to the poem: though he requires, in order to excel, considerable knowledge of the subject and superior taste, yet he is but an operator—a singer or a player, and not, strictly speaking, a musician.

Speculative Music is subdivided into Acoustical, Mathematical, and Metaphysical. [ACOUSTICS; HARMONICS; SOUND; TEMPERAMENT] Practical Music into Vocal and Instrumental, the several kinds of which are noticed under their respective heads. The chief component parts of practical music are, MELODY, HARMONY, and RHYTHM, to which we refer. See likewise ACCENT, AIR, CHORD, COMPOSITION, COUNTERPOINT, MODULATION, THOROUGH-BASE, TIME, &c.

MUSIC, HISTORY OF. The origin of music is involved in an obscurity which no ingenuity, no labour, has hitherto been able to dispel; analogy and conjecture, therefore, have supplied the want of facts, in the absence of any assistance except what doubtful histories and the fables of mythologists have afforded, which at best have held out but a dim light, and more often misled than aided the inquirer in his researches.

It has been supposed by some writers whose names stamp a value on all that has proceeded from them, that song and speech are coeval, an opinion which will hardly be disputed, if by song are meant sounds which, though vocal and sustained, are devoid of rhythm, governed by no scale, and consequently productive of no melody, in the modern acceptance of the word; but if the term is intended to signify a regular system of tunable measured notes, then we shall not hesitate to say that such advance towards art could only have been made by people proceeding fast in civilisation, and communing through the medium of a language adequate to all the ordinary purposes of man in a social state.

We are told by Lucretius, in a passage often quoted from the fifth book of his poem 'De Rerum Natura,' that the birds taught man to sing, and that the invention of musical instruments of the inflated kind was suggested to him by the sounds produced from reeds when the western wind blew over them:—

"the birds instructed man,
And taught him songs before his art began.
And while soft evening gales blew o'er the plains,
And shook the sounding reeds, they taught the swains;
And thus the pipe was fram'd, and tuneful reed."

This has certainly the merit of being very poetical, whatever reliance the historian may place on it. The same notion concerning wind instruments is found in Ovid's beautiful account of the transformation of the nymph Syrinx into reeds. But Thomas Aquinas, the "Angelic doctor," cited by Padre Giambattista Martini, in his 'Storia della Musica,' disdains to follow the example of the heathen author of the 'Metamorphoses,' or the disciple of Epicurus, and leave the origin of music to chance; on the contrary, the noble Italian saint informs us that the first man was endowed by the Creator with every kind of knowledge, and that he excelled in music, as well as in all other arts and sciences.

But quitting the ingenious guesses and fictions of poets and the reveries of enthusiasts, we find Jubal, the seventh in descent from Adam, mentioned in Scripture as "the father of such as handle the harp and organ." These terms, however, must not be understood quite literally; they are generic, and signify all instruments of the stringed and tube kind. The different versions vary in the translation of the original: the French render the word *harp* by *violon*. Though the earliest authentic record of music extant is that in Genesis, yet it is nearly certain that the Jews acquired their knowledge of it from the Egyptians. The whole generation of the Israelites led forth by Moses from their captivity were born in Egypt, in which it seems to be agreed music as an art originated; though Diodorus Siculus even denies that it was ever practised there: but his assertion is not only in opposition to Herodotus, and at utter variance with what Plato says, who travelled into that country to become acquainted with the arts and sciences, but is proved by modern discoveries to be the very reverse of truth. The fresco painting of a harp, found by Bruce in an ancient tomb near the ruins of Thebes, which is undoubtedly of very high antiquity, is an indisputable proof of the progress made by the early Egyptians in music. In form, dimensions, and ornament, this instrument might be mistaken for one of modern date, inasmuch that when a drawing of it was first shown in London considerable doubts were entertained of its fidelity. Forty years after, however, M. Denon bore testimony to the truth of Bruce's description and the accuracy of his sketch, since which Rosellini's 'Monumenti dell' Egitto' and Wilkinson's 'Ancient Egypt' have confirmed all that the two former had said on the subject. Other instruments have been found sculptured or painted on Egyptian monuments, several of which are in the British Museum, and they furnish evidence of the state of music in Egypt in the remotest times. These are sufficient proofs of early Egyptian knowledge in the musical art. That it continued to be cultivated in Egypt under the Macedonian dynasty there can be no doubt. Athenæus, in his account of a Bacchic festival given by Ptolemy Philadelphus,—the munificent patron of all the liberal and useful arts, who made Egypt the mart of the world,—tells us that more than 600 musicians were employed in the chorus, and that among these were 300 performers on the cithara, or lyre.

Of the music of the Hebrews, nearly all that is known is to be collected from the Scriptures, and the Bible is in the possession of every one. There we meet with the first recorded song, which Moses sang at the head of the tribes, after the miraculous passage of the Red Sea. To this responded Miriam the prophetess, having a timbrel or tambourine in her hand, and being attended by all the women, carrying the same instruments, and dancing. Music formed an essential part of every Jewish ceremony. The priesthood were musicians by office, which was hereditary: they were 4000 in number, divided into bodies, each of which had its chief or leader. At the dedication of Solomon's temple a prodigious band of priests, blowing trumpets, attended. Josephus tells us that 200,000 musicians were engaged; but as his statement is unsupported by scriptural history, we may venture to consider it as a mistake arising from some misapprehension, or else as a manuscript error. A Hebrew writer enumerates 36 musical instruments that were kept in the sanctuary, all of which, he says, the prophet-king David could play. These are reduced to 33 by another account. It is worthy of remark that many of them, under other names, are still met with in the East and in Egypt, and, as far as can be ascertained, very little changed from their original form. Martini has given, from a manuscript of 1599, what he believes to be specimens of the melodies sung by the Jews to certain Psalms; but they are printed in the obsolete notation, without bars, and having no words added to them by which the measure might perhaps have been made out, it is impossible to enter thoroughly into their meaning.

The music of the Greeks has engaged the notice of so many searching antiquaries and patient mathematicians—such profound learning and unwearied labour have been bestowed on it—it has provoked so much controversy, and the dispute has proved so barren, that we enter on the subject reluctantly, if not fearfully. But before proceeding further, we think it right to say that, after a diligent investigation of the subject, on which we entered with an unprejudiced mind, it is our decided opinion that what is now called Greek music has hitherto proved perplexing chiefly, if not solely, on account of the term having been misunderstood. We believe that by *mousike* (*μουσική*) the Greeks meant *poetry sung*, with some sort of accompaniment, and that the moderns have fallen into error by overrating the importance of the melodic part, treating this as the principal, and poetry only as an ally.

Music was a comprehensive term with the Greeks, embracing, among other things which we shall have occasion to mention, melody (*melopœia*, literally the *making*, or composition, of the song) and poetry. There

is no one, M. Villoteau remarks, who, after an attentive perusal of the ancient writers, is not convinced that eloquence, poetry, and melody were in early times governed by musical principles, that they were taught by the same master, and that the three arts were but one science. The Greeks never separated poetry from melody; the poet himself set the notes to his own verses, and in the early times sang them at the public games and festivals. The Greek tragedies were *operas*, observes Payne Knight, meaning, we presume, that they were in a kind of recitative; and he is borne out in his assertion by the best authorities. Aristotle, in his treatise on poetry, considers the *music* of tragedy as one of its most essential parts. The nature of this *music* is indicated by several writers, but is more clearly pointed out by Philodemus than by any other, in his work in abuse of music (one of the *papyri* found in Herculaneum, unrolled and published at Naples in 1793), wherein it is described as a melody nearly approaching ordinary speech; that is to say, recitative. Horace calls Apollo *the singer*. The ancient poets give us to understand that their verses were *sung*, and this is to be construed literally in the case of the Greek poets. Homer, according to tradition, sang his own epics. But it is needless to multiply proofs of a fact so generally received.

Admitting, then, that Greek poetry of all kinds—religious, epic, dramatic, &c.—was really sung, let us imagine what was meant by the word *singing*. It is not to be imagined that Homer, Tyrtæus, Pindar, &c., were singers, in our acceptation of the word; the supposition is too absurd to be entertained for a moment. But even allowing them to have been as perfect in the vocal art as the moderns are, would they have condescended to deliver their poetry in long flights of notes, in divisions, in trills, and in passages that render it difficult, and sometimes impossible, to get at the sense? If, however, they had attempted to make their “heaven-bred poesy” subservient to song, would they have found a patient audience?—Assuredly not; for the animating appeal, the interesting narrative clothed in poetical language, the pathetic description, were what the Greeks delighted in, and certainly would not have surrendered for the sake of a tune. Moreover, it must be recollected, and is a very important consideration, that when the art of printing was unknown, and manuscript copies of poems, &c., were unattainable by the people at large, on account of the expense, the multitude had no means of becoming acquainted with the productions of their poets but by hearing them recited; and as crowds assembled for this purpose, the best mode of rendering the voice of the reciter audible to many, and these congregated in open places, was, to pitch it rather high, and confine it to a small number of fixed musical notes. Such is still the practice, and with the same intent, in all cathedrals, and is called chanting—a usage which has doubtless been transmitted from the remotest ages. Such, too, is the method adopted by the *improvisatori*, whose art, we are persuaded, is of the highest antiquity, and whose singing, it is our belief, much resembles that of the ancient Greeks in delivering their verses. Those extemporaneous poets always require an instrumental accompaniment of a simple kind, to keep the voice in tune, and, as they confess, to animate them. The Greek reciters also were accompanied either by the lyre or the flute, and probably for the same purposes. The flute was the companion of elegiac poetry; the lyre of the epic and the ode.

By what is called Greek music, therefore, we understand the union of poetry and music, the former of the two exercising the greatest sway over the mind, because expressing noble sentiments, gracefully inculcating religion and morality, teaching obedience to the laws, exciting generous feelings, and inspiring patriotism and courage by the praise of those who had distinguished themselves by their public services and their valour. It is thus we account for the effects said to have been wrought by ancient music; for it is impossible that Plato should have been thinking of mere vocal melody and the sounds of mean and imperfect instruments, when he said that no change can be made in music without affecting the constitution of the state—an opinion in which Aristotle acquiesced, and which Cicero afterwards adopted. It is not to be credited that the laws of Lycurgus, set to measured sounds by Terpander, were turned into a song, or that this Lesbian musician quelled a sedition in Sparta by singing some pretty air to the mob. It is absurd to suppose that when Polybius tells us of a savage nation civilised by music, he means to say, by coarse pipes and guitars;—and not less ridiculous is it to imagine that men were raised to the rank of chiefs and the dignity of legislators, solely on account of their taste in singing, or their skill on the lyre and the flute.

We cannot quit the subject of the vocal music of Greece without adding a few words concerning the Greek *Nomes* and *Scolia*. The former (from *νόμος*, *nomos*, a law) were so called, says Plutarch, because they were not allowed to transgress certain melodic rules by which they were characterised, and were at first hymns to the Gods. The latter were songs of a less restrained kind, sung at banquets and entertainments, by great proficient; hence Hesychius derives the term from *σκολιός* (*skolios*, difficult to sing). But others think that the word should be rendered literally,—*crooked*, following a tortuous course,—because, at table, it did not pass regularly, but only to those who were skilful singers. Plutarch, on the authority of Pindar, tells us that the *scolia* were invented by Terpander. Muller, in his ‘History of the Literature of Ancient Greece,’ considers Terpander to “have been properly the founder of Greek music.” He also invented the seven-stringed lyre, and was probably the first to set poetry to music.

As to the instrumental music of the Greeks, we confess our inability to treat the subject in a satisfactory manner. The accounts given of it by the ancient writers are either so suspicious or so indefinite, that nearly all our labour in endeavouring to gain some knowledge of its nature has been expended in vain. Having Bianchini’s learned work on ancient instruments before us, we are enabled to form some opinion of their capabilities, and our opinion is not in their favour. They appear to have been rude, and suited only to music of the simplest description.

The musical scale, or disdiapason, of the Greeks comprised two octaves, the lowest note of which was *a*, the first space in the base of the moderns. This was divided into five Tetrachords, or subdivisions of four sounds in each, the extremes being at the distance of a fourth. [TETRACHORD.] The notes or sounds were represented by the letters of the alphabet, great and small, which, in order to extend their application and distinguish the various modes, were placed in different positions—the direct, the averted, the inverted, and the horizontal; and these were, as occasion required, altered in form. The time or duration of the notes was known by the long and short syllables to which they were set; the long syllable was in duration as two, the short as one. But we know only the comparative times of these; of the positive lengths of notes we remain in ignorance. The movement however of Greek music is supposed to have been slow. The modes were, according to Alypius, fifteen in number: Aristoxenus makes them thirteen, each a semitone distant from the next in order. Under the word *MODE* we have given the table of Alypius; that of Aristoxenus, the oldest of the Greek writers on music, commences with the Hypodorian, the lowest, and varies considerably in the key-note from that of Alypius, and there are no certain means of reconciling the discrepancy.

By the word *μέλος* (*melos*) the Greeks generally signified what we call air, or something like it; but sometimes, Twining remarks, “they used it in the sense of *ἁρμονία*, that is, *melody* abstracted from rhythm, or time; sometimes for *measured melody*; and sometimes as equivalent to *song*, including melody, rhythm, and words.” By *ἁρμονία* (*harmonia*) they intended simply to express, as we have in a former article observed, the proper relationship of one sound to another—the pleasing agreement of intervals; that is to say, melody. Metastasio believes that by this term the Greeks signified what we mean by melody, founding his opinion on the following passage from Plato (*De Legib.*, lib. ii.):—*The regulation of the movement is called rhythm; but the regulation of the voice is called harmony.*

The long-contested question, whether the Greeks understood counterpoint, or music in parts, seems now to be set at rest, and determined in the negative by a preponderating weight of authority and a large majority of voices. To what we have before remarked on this subject [HARMONY], we now add, that further inquiry and reflection have only confirmed the opinion we have long entertained, namely, that though the ancients, by mere accident, if not from experiment, must have been acquainted with the effect of simultaneous sounds, nevertheless that which we call harmony formed no part of their musical art, either theoretically or practically. And we repeat our belief, that in the union of poetry and song, which undeniably operated with such amazing force on all classes of the people,—which inflamed them with ardour,—softened them into obedience, and melted them into pity,—music was but the ally of verse.

Of their instrumental music, or music without the voice, we are told that the flute-players by profession—who certainly were exceedingly encouraged and most extravagantly paid for their services in the later times of Greece—piqued themselves chiefly on the strength of the sounds they could produce from the instrument; and that the trumpeters thought themselves fortunate if, in their contests at the public games, they escaped without the rupture of a blood-vessel by the violence of their exertions. It is to such performances Aristotle must allude in saying, “I disapprove all kinds of difficulties in the use of instruments, and, indeed, in music generally; I mean such tricks as are practised at the public games, where the musician, instead of recollecting what is the true object of his art, endeavours only to flatter the corrupt taste of the multitude.” Facts and remarks like these do not lead to any favourable opinion of Grecian performers. It is likely however that they pleased most when they played the airs set to the favourite poems and popular verses. And there seems some reason to believe that they extended these by additions, sometimes studied, but often extemporaneous, resembling what are in modern language called variations, or an amplification of the theme.

It was a tradition that Cadmus, with his Phœnicians, introduced music into Greece. But Plutarch, in his ‘Dialogue on Music,’ first makes Lycias, a professor of the art, repeat the statement of Heraclides, that Amphion, the son of Jupiter and Antiope, taught the Greeks to compose and sing lyric poetry: then, by a second interlocutor, Soterichus, contradicts the first, assigning to Apollo the merit of having converted Greece into a musical nation. The invention of the lyre of three strings is given to the Egyptian Mercury, or Thoth; that of seven strings, to the second or Grecian Mercury. Chiron, the centaur, taught Achilles music. Orpheus was the musical pupil of Linus, and master of Hercules. Then came Olympus, Terpander, and others. Terpander is said to have appeased an insurrection in Lacedæmon by his songs. He rendered a most important service to the art by inventing a method of representing musical sounds. Till

his time music was quite traditional, and depended on the memory, and sometimes the caprice, of the performer. Plutarch says of him, on the authority of Alexander, an historian, that he took Homer for his model in versification, and Orpheus for the style of his melodies. The musical compositions of Orpheus, the same writer adds, were wholly original.

Many very celebrated players on the flute are mentioned in musical history. Damon taught Pericles and Socrates the use of this instrument. Antigenides and Dorion were also renowned for their talents. But the performer who excited most admiration was of the gentler sex. Lamia was no less distinguished by wit and ability than by personal charms. After captivating many by her skill as a flute-player, and by her beauty, Demetrius Poliorcetes became violently enamoured of her, and, through her influence, conferred such extraordinary benefits on the Athenians, that they dedicated a temple to her. Whatever may have been the style of flute-playing, or of the music, it is certain that in Greece the performers were in great favour. Xenophon says, that if an indifferent player wished to pass for one of superior talent, he must furnish his house richly, and appear abroad with a large retinue of servants, as the great performers do. It is said that a flute used by a celebrated Theban musician, Ismenias, cost nearly six hundred pounds sterling.

Pythagoras, of whom an idle story was long current, about a blacksmith's shop, hammers, and anvils, contributed much to the improvement of music by his calculations and philosophical experiments. To him also is attributed the addition of an eighth string to the lyre. His notion concerning the music of the spheres—music produced by the motions of the heavenly bodies—was one of those whims in which great geniuses are apt, now and then, to indulge. He was of the sect of severe musicians, of those who reduced music to mathematical precision, and regulated all sounds by calculations, allowing no licence to the ear. Of an opposing school was Aristoxenus, born at Tarentum in Italy, about 350 years B.C., who thought the ear entitled to share with mathematical principles in determining the effect of modulated sounds. He was a most voluminous writer on many learned subjects. Of these his 'Elements of Harmonics' are all that have reached us, and stand first in the collection published by Meibomius. Next in that excellent work is an 'Introduction to Harmonics,' by Euclid, the geometrician; and this is followed by his 'Section of the Canon,' containing short and clear explanations of the constituent parts of Greek music. Ptolemy, an Egyptian, and not the astronomer, wrote a treatise in three books on 'Harmonics,' which Dr. Wallis printed, with a Latin version, a preface, and appendix, in 1682. He enters at large and deeply into the subject, and his principles have a tendency to reconcile the hostile sects of Pythagoreans and Aristoxenians. This object was pursued with success, by Sir F. H. Styles, in his paper published in the 51st volume of the 'Philosophical Transactions.' In Plutarch's 'Dialogue on Music' much information concerning ancient Greek music is to be found, but not of the most valuable kind. Aristides Quintilianus wrote a treatise on music, printed in the collection of Meibomius, which has proved a useful work to all subsequent writers on the subject. He was enthusiastic and fanciful, but in matters of fact and calculation is worthy of confidence.

The Romans acquired all their knowledge of the arts and sciences from the Greeks; their music therefore in no way differs from that of the latter; though they must have had some kind of song before any direct intercourse had taken place between them and the polished nations of Greece. It is certain that the art was never advanced by that warlike people, notwithstanding the share it had in all their religious ceremonies and public games, and the use made of it to animate their troops and add effect to their triumphs, and though it formed an essential part of their theatrical exhibitions of every kind, and was even adopted, or affected to be adopted, as a profession by one of their emperors.

The importance of music in the estimation of the early Romans is shown by a regulation attributed to Servius Tullius, who, in dividing the people into classes, directed that two whole centuries should consist of trumpeters, blowers of the horn, &c., and such as, without any other instrument, sounded the charge. It is further proved by a law of the Twelve Tables, which limited the number of players on the flute at funerals to ten. And another of those laws enacted, that at the praises of honoured men in the assemblies of the people, there should be mournful songs accompanied by a flute.

That the Roman drama was in some way musical, is proved by the title, or *didascalia*, prefixed to each of Terence's plays. A further proof of this is found in the Institutes of Quintilian, where, after showing the necessity of instructing children in music, he adds, "that he does not desire that they should learn such music as prevails on the stage, the modulations of which are so intermixed with impudence and wantonness, that they may justly be charged with having extinguished the poor remains of manly courage which had been left." That the theatrical music of the Romans was similar to that of the Greeks there seems to be little doubt; that it was distorted by the performers in Quintilian's time is very likely.

It is remarked by Dr. Burney, that even during the Augustan age the Romans had no sculptor, painter, or musician, and but one architect, Vitruvius; those, he says, "who have been celebrated in the arts at Rome having been Asiatics or European Greeks, who came to

exercise such arts among the Latins as the Latins had not among themselves. This custom was continued under the successors of Augustus; and those Romans who were prevented from going into Greece contrived in a manner to bring Greece to Rome, by receiving into their service the most able professors of Greece and Asia in all the arts."

The Roman writers on music are few, and almost worthless. Vitruvius, in his work on architecture, treats of the sound of the voice, of reverberating vases, and of a *water-organ*; but no one has yet been able to discover what he means by this instrument. He also endeavours to make plain the harmonical system of Aristoxenus, though he acknowledges the difficulty of the task. St. Augustine wrote on rhythm and metre; Boethius devotes five books to music, merely to explain the principles of harmonics; and Aurelius Cassiodorus treats of music, among other things, but his work, or sketch, is said to consist of little more than some general definitions and divisions.

There is every reason to conclude that music remained stationary till the 10th or 11th century. The Romans, having borrowed the art from Greece, seem to have been convinced of its perfection in the state in which they received it, for there is no evidence of their having attempted to enlarge its narrow boundaries, or in any way to improve it; though a people of more ingenuity and taste would have advanced it at least a few steps towards that point which, however slowly, it has now attained.

In the primitive Christian church the service consisted partly of music, which is supposed to have been chiefly that of the Greeks, with an admixture of Hebrew melody. Menestrier conjectures that the early ecclesiastical manner of singing was like that of the ancient theatre, and Dr. Burney concurs in this opinion; though we cannot but think it more likely that the "songs of Zion," as performed in the Jewish temple, and the chanting of the hymns at the Pagan altars, were chosen as vocal models for devotional purposes, rather than the airs, or recitatives, in which the comedies of Plautus and Terence were delivered. Towards the end of the 4th century, St. Ambrose digested a musical service for the church of Milan, which is called the Ambrosian chant, and was founded on four of the Greek modes. About the year 600 Gregory the Great enlarged and much improved the chant of the church, by the admission of four other modes, and gave it that form which it still retains in the Roman Catholic service, and in which it is known by his name. According to Bishop Stillingfleet, music was introduced into the English church by St. Augustine, in the latter part of the 6th century, and was subsequently much improved by St. Dunstan, an excellent musician, who, it is said, furnished some few churches with an organ.

The organ—the most majestic and comprehensive of all musical instruments in its present almost perfect state—is supposed to have been an improvement of the hydraulicon, or water-organ, of the Greeks. The first mentioned in musical history was sent, in 757, as a present to King Pepin, from the Byzantine Emperor Constantine Copronymus. In the 10th century the organ was in use in several parts of Europe; but it is reasonable to conclude that it was then exceedingly simple, possessing little power, and rude in mechanism: nevertheless, it may fairly be assumed that the invention of the organ hastened the discovery or practice of harmony. [ORGAN.]

To Guido, of Arezzo, we are indebted for many of those improvements in music which led to our present system; though the origin of counterpoint has been erroneously ascribed to that active and ingenious ecclesiastic. [GUIDO, in BIOG. DIV.] Magister Franco, a member of the cathedral of Cologne in the 11th century, is considered as the inventor of what in the middle ages was called *Cantus Mensurabilis*, which meant, notes showing, by their forms, their time or duration. Most of those, however, have fallen into disuse, for the shortest in his table is the semibreve. Nevertheless his system, carried out further by De Muris, and by degrees extended, is that of the present day, and is so sound in principle that it probably will never be abandoned.

From the 11th to the 15th century, scarcely anything is known of the progress of music. For its history from the latter period, we refer to the biographical sketches of its most eminent professors which appear in the Biographical Division of our work;—to the articles ACADEMY, CONCERT, OPERA, ORATORIO, &c.;—to the names of musical instruments; and to all the terms under which musical compositions of every kind are described. From these sources may be gathered much of the information, if not all, that will be required by the general reader.

MUSK, *Medical Properties of*. Musk, taken in the dose of a few grains, rouses the energy of the digestive organs; and it soon afterwards produces sympathetic phenomena, the powers of the whole animal system appearing suddenly increased. By repeating the dose till half a drachm or a drachm is consumed, the active principles penetrate the whole frame, influencing all the tissues, and exciting effects demonstrative of its stimulating property; the blood circulates with more force, accompanied sometimes with bleeding from the nose: the perspiration and other secretions are perceptibly increased. Other effects prove that it also acts on the brain, spinal chord, and ganglionic nerves, such as tendency to sleep, convulsive movements, and particularly spasms of the chest and abdomen. Owing to idiosyncracies, musk produces in some persons very extraordinary effects, at times so violent that they cannot bear the faintest odour of it.

Musk has been recommended in typhus and other fevers, when there exist low delirium, hiccup, twitching of the tendons, &c. But its beneficial action is not so constant as to justify much reliance upon it. It is much more useful in diseases purely nervous and spasmodic, where no inflammatory action has preceded or is present. Hence even in epilepsy, as well as hysteria, it is serviceable. In laryngismus stridulus, called epileptic croup, or crowing respiration, of children, it is very useful. In combination with ammonia it is useful in arresting a tendency to gangrene. Likewise in retrocedent gout it has proved successful. It was found of little avail in severe cases of Asiatic cholera, though useful in the milder forms of it.

Artificial musk should never be used for medical purposes.

MUSKET. [ARMS.]

MUSLIN, a thin cloth, or fine calico, made of cotton. The name is supposed to be derived from Masalia, since called Masulipatam, near Madras, from which place such fabrics were first imported into Europe. Until the early part of the present century all the muslin used in Europe was the manufacture of India. The durability of the India muslins is not, as some have supposed, the consequence of any superiority in the quality of the material of which they are made; for the raw cotton of India is far inferior to that which is used for these fine fabrics in Europe, and which is brought from America and from Egypt. The excellence of India muslins is owing to the skilfulness and patience of the spinners and weavers in that country. Some of the muslins of India, and especially those of Dacca, are of the most astonishing degree of fineness, so as to justify their poetical description as "webs of woven wind." Such however has been the result of the inventions of England in this branch of industry, that not only are the muslins of British manufacture now used at home, almost to the exclusion of those woven in India, but large quantities are exported to all parts of the world, and find their way even far into the interior of India. Some of the kinds now made by machinery are of exquisite fineness. [COTTON MANUFACTURE.]

Paisley and Manchester are the chief seats of the muslin manufacture. Glasgow houses now carry on a vast trade in worked or embroidered muslin. At first, the women and girls in the district within twenty miles of that city were employed in the work; but afterwards it was found that an abundant supply of such labour could be obtained in the north of Ireland. Even so early as the beginning of the present century, it was estimated that 20,000 females earned a living at this muslin work. When working, the muslin is stretched over a hoop, and kept in its place by means of another hoop slightly larger in diameter; the hoops are either held between the chin and the knee, or supported on some kind of stand. The embroidering is a kind of chain stitch, produced by the needle. There are, however, other kinds of sewed muslin work for which no hoop or tambour is required. The extension of the trade to Ireland was chiefly determined by the circumstance that, when machine flax-spinning was introduced in that country, the hand-spinners were thrown out of employment, and were glad to accept the work which the Glasgow firms offered to them. Until about the year 1830 the patterns for the muslin-workers were printed from engraved blocks, which in some cases cost as much as five guineas each; but the lithographic press has greatly increased the rapidity and lessened the cost of producing patterns; and, as one among many favourable consequences, the artistic merit of the designs has been much increased. Agents for the wholesale houses visit the country districts, seek out and employ the women and girls, supply them with the muslin, fetch it away when finished, and pay them for their work. In busy times, agents for two or three firms will compete with each other at the same place; and the usual result, a rise in wages, is produced. The earnings begin at 6d. per week for young workers, and rise to 6s.; first-class hands occasionally earn 10s. All the women and girls work at their own homes, the employment being essentially a domestic and not a factory one. It was estimated, so far back as 1851, that not less than 600,000l. was thus paid annually to women and girls for muslin-working, chiefly in the west of Scotland and the north of Ireland.

A somewhat analogous, but still distinct, application of female labour is noticed under EMBROIDERY AND SEWING-MACHINES.

MUSTARD, OIL OF. White mustard-seed yields about 36 per cent. of a yellow fixed oil, which appears to consist of glycerin united with two acids,—erucic acid ($C_{44}H_{82}O_4$) and oleic acid. In addition to this fixed oil, mustard yields when moistened an essential oil [FERMENT] which is the sulphocyanide of allyl (C_6H_5S , CyS). This body may be obtained in a state of purity by rectifying the essential oil of mustard, and also by distilling together sulphocyanide of potassium and iodide of allyl.

Sulphocyanide of allyl is a colourless oil possessing an acrid taste, and the excessively penetrating and pungent odour which is so well known in mustard paste. It is only slightly soluble in water, but soluble in all proportions in alcohol and ether. It has a powerful blistering effect when applied to the skin.

Sulphocyanide of allyl rapidly absorbs ammonia, producing thio-sinamin.

Digested with hydrated oxide of lead, it forms *sinapoline*, or *diallyl-urea*.

MUTINY ACT is an annual measure passed by parliament to confer on the executive government the right to raise and maintain in this country for the ensuing year a standing army, consisting of a specified number of men, and subject to the laws and discipline of war comprised in the act itself, and in the articles of war issued annually under authority of the statute by her Majesty.

Laws have, at various times, been made by the authority of the crown for the maintenance of discipline in the army when in garrison, on a march, and in the presence of an enemy; these have been briefly hinted at in the article on MARTIAL and MILITARY LAW, and may be seen at length in Grose's 'History of the English Army' (vol. ii.); but the code which is now in use is one of the first-fruits of the Revolution in 1688. Previously to that event the crown, except during the civil wars and the subsequent protectorate, had, at least practically, the supreme power over the militia (that is, over the whole military force), which, with or without the consent of the nation, might be called out and employed as long as pay and quarters could be obtained for the troops. But the efforts then recently made to carry out a series of measures tending to the maintenance and extension of arbitrary power in the crown, joined to the increasing jealousy of the people for their civil and religious liberties, led the two houses of parliament to take the earliest opportunity, after the new king had been called to the throne, of expressing in some public act of legislation their authority over the regular troops of the nation; and an opportunity almost immediately presented itself, on occasion of a serious mutiny taking place in the army. While the Royal Scotch and Dumbarton regiments, under Marshal Schomberg, in their progress to the coast for the purpose of being embarked for Holland, were quartered at Ipswich, a large body of men refusing to proceed to their destination, disarmed their officers, seized the military chest, and, with four pieces of cannon, began their march for Scotland. Being pursued by General Ginckel, with three regiments of Dutch dragoons, they surrendered at discretion; but, in consequence of this event, and on the spur of the moment, a bill was passed (April 12th, 1689) by which the army was put at once under the control of the law with respect to discipline, and under its protection with respect to pay and quarters.

The enactments of this measure were particularly directed against the crimes of mutiny and desertion, for which the bill was immediately required; but the Act itself begins by laying down as maxims that the raising or keeping a standing army in the country in time of peace, unless it be with the consent of parliament, is against law; and that no man can be forejudged of life or limb, or subject to any kind of punishment in any other manner than according to the established laws of the realm. It then states that it is judged necessary, by their Majesties and the parliament, during the present time of danger and for the defence of the Protestant religion, to continue and augment the forces which are now on foot. Avoiding the acknowledgment that any power exists in the crown for the appointment of courts-martial, it authorises their Majesties to grant commissions to general officers to assemble such courts for the purpose of trying and punishing such offences as mutiny and desertion. Provisions are also made that nothing in the Act shall exempt an officer or soldier from the ordinary processes of law; that it shall not concern the militia troops, and that it shall only continue in force till the 10th of November in the same year. The Act has ever since, with one exception, been annually renewed: after the bill which passed in April, 1697, for one year as usual, had expired, no other was passed till March, 1702; and, on a few occasions, the bill has been suffered to expire for several days before the following one received the royal assent.

The Mutiny Act has, with time, varied in many particulars from that which was first passed, but it has been uniform in all its principal points; such as the dependence of a standing army on the consent of parliament, and the subjection of military men to all the processes of ordinary law. Instead however of the original formula above-mentioned, by which the reason of keeping up a military force was expressed, the Act now asserts that it is judged necessary by the crown and parliament to continue a body of forces (the number being exactly specified) for the safety of the United Kingdom, the defence of the possessions of her Majesty's crown, and the preservation of the balance of power in Europe. In all the Acts which passed down to the commencement of Queen Anne's reign the articles were few in number, and some of them were very ill defined; but, from that time, parliament seems to have intended to exercise a general legislative jurisdiction over the army. Many new articles were then inserted; others have since been added, as the want became apparent; and the Mutiny Act may now be considered as a good general code of law, in which are defined strictly but briefly all military offences of the higher class, and, as precisely as possible, nearly all those of minor importance. The military offences of the higher order, comprised in eleven classes, consist in any commissioned or non-commissioned officer, or soldier, exciting mutiny, or in not using his best endeavours to suppress

it, or not giving information thereof without delay to his commanding officer; in misbehaving before an enemy; shamefully abandoning or delivering to the enemy any garrison, fortress or post; compelling the governor of such garrison to do so; using means to induce any one to misbehave before the enemy, or shamefully to abandon or deliver up any garrison, fortress, or post committed to his charge; quitting his post without leave, or sleeping at his post; holding correspondence with, or giving advice or intelligence to the enemy; or entering into terms with any enemy or rebel without licence; using or offering violence to a superior officer, or disobeying his lawful commands; or offering violence, whilst confined in a military prison, to any visitor or superior officer in the execution of his duty; and, finally, in deserting the service. For all these offences the Act prescribes "death, or such other punishment as a general court-martial shall award;" provided always that two-thirds of the court do concur in any judgment of death. The Act then enumerates the military offences of minor importance, and the punishments which may be assigned in respect of each. Embezzlement, fraudulent misapplication, wilful damage, theft or connivance at the same, of money, provisions, forage, arms, clothing, ammunition, or other stores, by any paymaster, commissioned officer, or other person employed in the war department or concerned with the care or distribution of such property, makes the offender liable to not less than four years' penal servitude, or to fine, imprisonment, dismissal from the service, reduction of warrant or non-commissioned officer to the ranks, with incapacity to serve her Majesty, as a general court-martial shall think fit, in addition to his liability to make good the loss. It is in the power of any court-martial to award corporal punishment, not exceeding fifty lashes, for disgraceful conduct, misbehaviour, or neglect of duty;—of any general, district, or garrison court-martial to award in addition imprisonment with or without hard labour, or solitary confinement;—of any general court-martial in addition to award forfeiture of additional pay, good conduct pay, pension on discharge, annuity or medal for past or future services;—and such additional forfeiture may be awarded by any district or garrison court-martial for desertion or for disgraceful conduct by the offender in wilfully maiming himself; tampering with his eyes; wilfully by any act producing or aggravating disease or delaying his cure; malingering, or feigning disease; stealing government stores; stealing from any officer or comrade, regimental mess or band, or feloniously receiving the products of such offence; making or procuring false accounts; embezzling public money; committing any other offence of a felonious or fraudulent nature, or for any disgraceful conduct being of a cruel, indecent, or unnatural kind. He is also liable to forfeit his pay when absent from duty improperly, or in consequence of his offences, and to be subjected to stoppage of pay to make good bounties fraudulently obtained or loss or damage inflicted by his offence. There is also power to dismiss a soldier from the service with ignominy, or mark a deserter with the letter D in ink or powder indelibly, and the terms of imprisonment which may be awarded by the different courts-martial are specifically ascertained.

Besides the above laws, which relate particularly to the discipline of the army, the Act defines the constitution and powers of courts-martial [COURTS-MARTIAL]; it contains provisions relating to the enlistment of recruits [DISCIPLINE; ENLISTMENT], the issue of pay and marching money, the quartering of soldiers, and the supplying of carriages for the conveyance of troops and baggage. The Act moreover contains a repetition of the original clause in which it is declared that the ordinary course of law is not to be interfered with when a soldier is accused of any felony or misdemeanor or any crime or offence, other than the misdemeanor of refusing to comply with an order of justices for the payment of money, provided that no soldier be taken out of the service for a debt under 30*l.* or for breach of contract, except by desertion as an apprentice from his master when bound to him for seven years.

The Mutiny Act is declared to be applicable to all persons employed in the recruiting-service; to the forces of the Indian army while in any part of the United Kingdom, and till their arrival in India; to the officers and men employed in the service of the artillery and engineers; to the corps of the sappers and miners; to the military surveyors and draughtsmen in the ordnance department; to foreign troops serving in any part of the British dominions abroad; and to all storekeepers and all civil officers of or under the war department at home or abroad. Its provisions also extend to the islands of Guernsey, Jersey, Alderney, Sark, and Man; but not to any of the militia forces, or yeomanry, or volunteer corps of Great Britain or Ireland. It applies also to officers holding rank by brevet, though not to such as are on half-pay. An effort was made in 1749, when the bill was introduced as usual into parliament, to subject officers of this latter class to martial law, but the clause was abandoned by the minister. Before the union of Ireland with Great Britain there was a separate Mutiny Act for the former country, but now the same Act applies to both. The officers and troops of the Indian army are subject to their own Mutiny Act, which however agrees generally with that of the forces of the British army.

Previously to the year 1750 the members of courts-martial were bound by an oath not to disclose the ground on which they gave their votes; but in that year the Act was so far mitigated as to release them from such oath when required to give evidence in any court of justice

or court-martial. The power of disclosing, in that case only, the votes or opinions given is implied in the forms of the oaths which are now taken by the judge-advocate and members of the court-martial, and which are printed among the schedules to which the Act refers. The Act of the same year also contains a clause, in which it is stated that no sentence pronounced by a court-martial, and signed by the president, shall be more than once revised; previously to that time a general-officer had power to order the revisal of any sentence as often as he pleased, and thus he might retain in confinement a man who had been acquitted on a fair trial.

The gradual extension of the provisions of the Mutiny Act to those military offences which may be considered as secondary in the scale, does not seem to have been noticed on behalf of the crown further than by the occasional reservation of its right to make Articles of War for the better government of the forces, which is expressed in the acts passed during the reign of Queen Anne. In the first year of George I. this right of the crown was formally allowed; and the clause containing it has been repeated in all subsequent Mutiny Acts, with the provision that no person within the United Kingdom and British Isles shall be subject to penal servitude, or to any punishment affecting life or limb, for crimes specified in the Articles of War, except such as by the Mutiny Act itself are liable to the same punishments.

The Articles of War which are at present in force, and which have from time to time been promulgated, are divided into five sections comprising together 160 articles. Many of these correspond exactly to clauses in the Mutiny Act; others, though relating to subjects in the latter, define the particulars of the crime and the punishment applicable to it with more precision; and there are articles which have no counterparts in the act. The first section relates to the duties and obligations of officers and men, including the forms of enlistment; the second to crimes and punishments, being necessarily much more specific and detailed than the statute, the object of the latter being generally to confer powers and ascertain the limits of their exercise; the third to courts-martial; the fourth to rank among officers; and the fifth to the persons who are subject to the Articles of War.

The above articles, being made by the crown as head of the army, are to be obeyed as being the commands of a superior officer; but in the opinion of writers on military law, the legality of the articles may itself become the subject of examination in a court-martial; whereas the Mutiny Act must be obeyed without inquiry.

The Marine Mutiny Act, closely resembling that which has already been described, is also a statute passed annually, and is applicable to the marines when they are on shore.

The Act on which are founded the Articles of War for the Navy was passed in the 22nd Geo. II., and this consolidated all the laws previously made for the government of the ships and vessels bearing royal commissions, as also of the forces at sea. Among the offences which in the Act constitute the crime of mutiny, are, the running away with the ship, or with any ordnance, ammunition, or stores belonging to the same; neglect of duty; joining in or using means to produce any mutinous assemblage of persons; uttering mutinous or seditious words, or concealing any mutinous intention; and striking an officer or disobeying his lawful commands. Of the thirty-six articles, nine relate to crimes for which the punishment of death, without discretion in the court-martial, is awarded; and there are twelve to which are assigned "death, or such other punishment as the nature and degree of the crime shall be found to deserve." Two of these were originally in the former class, and the qualifying clause was added in the 19th Geo. III. Except this alteration, none has been made in the Navy Act since it was passed.

MUZARAB, that is, a Christian living under the sway of the Arabs. Various etymologies have been assigned to this word, but the real derivation of the word *Muzarab* is the Arabic *Mustarab*, afterwards corrupted into *Muçarab*, which means a man who tries to imitate the Arabs, or to become one in his manners, language, and habits; and who, although knowing Arabic, speaks it like a foreigner. This name was given by the Moors of Spain to all Christians living under Moslem jurisdiction in Cordova, Seville, Granada, Toledo, and other large cities.

But the word *Muzarab* is better known to us as connected with the ancient liturgy of the Goths, which governed the Spanish church down to the 12th century, and was called "*Muzarabic office*" (*Missal Muzárabe*), owing to its being preserved by the *Muzarab* Christians of Toledo during the time of their subjection to the Arabs. The fate of the *Muzarabic* liturgy is singular enough. Though involving the same doctrines, it differed widely from the other offices of the church; it also contained many hymns composed by St. Eugenius, St. Ildefonso, St. Julian, St. Leander, and other great luminaries of the Visigoths. To produce uniformity in this respect, and substitute the Roman for the Spanish missal, became the principal aim of the holy see. Early in the 10th century a legate arrived in the Peninsula from Rome, sent by John X.; but the report which he made on his return proved to be a favourable one, and by the decision of a council, held at Rome in 924, the *Muzarabic* office was not only sanctioned, but even praised. Another attempt, made in 1064, under Alexander II., had a similar result. Again, in 1067, new legates were sent, with a positive injunction to insist on the abolition of the ancient service; but the Spanish

prelates resisting the innovation, the subject was laid before a council assembled at Mantua, and the Spanish missal was once more declared Catholic and orthodox. Still the holy see persisted in its object. No artifice or intrigue was spared; and the court of Castille was divided into two hostile factions, one in favour of and the other against the introduction of the Roman ritual. In the perplexity occasioned by this dispute the two parties resolved to leave the decision to the judgment of God, and the expedient adopted to discover the divine will was this: two wild bulls were procured, the one to represent the Roman, the other the Muzarabic ritual, and, in the presence of the king and the court, were matched against each other. After a bloody conflict, the *Muzarabic* remained victor. But this result did not deter Gregory VII. In 1087 the trial was repeated: a champion was chosen on each side, and the decision left to the fate of arms; but again victory was in favour of the ancient liturgy. Fire was then tried, and both missals were cast into the flames; but, if we believe the archbishop Don Rodrigo, who was present at the ceremony, the success was still more signal; for no sooner did the Roman volume touch the fire, than it jumped out of the flames half burnt, while the Spanish remained for a considerable time in the midst of them without receiving the least injury. The object was at last gained by other means. Alfonso, the renowned conqueror of Toledo, was won over to the interests of Rome, and, after much trouble and difficulty, he prevailed on the prelates of the kingdom to receive the universal office; and from that moment the *Muzarabic*, although not publicly condemned, fell into disuse. There is however still a chapel in the cathedral of Toledo where mass is performed every day agreeably to the *Muzarabic* ritual. It was founded by Cardinal Ximenes de Cisneros.

(Masdeu, *Historia Critica*, lib. ii.; Mariana, *Historia General de España*, lib. ix., chap. xviii.; *Missale Gothicum secundum Regulam Beati Isidori Hispalensis*, Romæ, 1804.)

MYCOMELIC ACID. *Mycomelinic Acid*. [URIC ACID.]

MYELITIS. Inflammation of the substance of the spinal cord. The spinal cord is liable to the same inflammatory affections as the brain. [MENINGITIS.] It is covered like the brain with membranes, which may be diseased independent of the substance of the cord, which like the soft part of the brain may also be diseased independent of its membranes. Inflammation of the cord and its membranes is a frequent accompaniment of a similar disease on the brain.

The membranes of the cord may be inflamed separately or together. The dura mater of the cord may be inflamed on its free or its adherent surface. This is sometimes the case in caries of the vertebræ. This inflammation may be attended with effusion or ulceration. The spinal arachnoid and pia mater may also be inflamed, and the same results observed as in the same membranes in the brain. These membranes are red and injected to a considerable extent, and serum or lymph are effused according to the severity of the inflammation.

The symptoms of inflammation of the different membranes cannot be well made out. The one great characteristic of all these inflammations is intense pain. This pain extends along the spine, and passes to the limbs, and is not unfrequently mistaken for rheumatic pain. With the pain there is a tendency to the disturbance of the muscular action. There may be rigidity or tetanic contraction of the muscles of the back, amounting in some cases to perfect opisthotonos. The muscles of the lower extremities may be affected in the same way. There may be also retention of urine, priapism, and obstinate constipation. In the commencement of the disease neither the pulse nor the tongue are much affected, but as the disease advances the pulse becomes rapid and the tongue brown, as the patient falls into a low typhoid condition.

The treatment in these cases should consist of opiates to alleviate the patient's sufferings, and of local bleeding, and purging with neutral salts. The hot bath in the acute stage, with setons, moxas, and leeches in the chronic stage should be employed. Mercury is not recommended.

Inflammation of the substance of the cord occurs independent of any affection of its membranes. This may also occur idiopathically, or as the result of accident. The symptoms of inflammation of the cord are very varied, according to the part of its structure which is affected. Tracing the inflammation from above downwards, all or any of the following symptoms may be observed. Convulsions of the muscles of the head and face, difficulty of articulating, or an entire loss of voice, spasm of the muscles of the jaw, difficulty in swallowing, irregular or spasmodic breathing, palpitation or intermittent action of the heart, constriction of the chest, dyspnoea, nausea, and vomiting, pains in the bowels, sense of a cord tied round the belly, difficulty in making water, retention of urine, incontinence of urine, constipation, involuntary evacuations, convulsions of the voluntary muscles, and palsy.

If the seat of the disease is above the origin of the phrenic nerves, or the third cervical vertebræ, death speedily takes place, as the nervous influence is no longer transmitted to the diaphragm, and other muscles of respiration. When the injury is below the origin of the phrenic nerves, or at the level of the fifth and sixth cervical vertebræ, the inspiration is free, but the expiration is laborious from paralysis of the intercostal and abdominal muscles. The patient can yawn, but cannot sneeze. The upper extremities are also usually paralysed in this case. If the inflammatory affection is a little lower down, as opposite the seventh cervical, the palsy of the upper extremities is

incomplete, but that of the trunk and lower extremities is complete. When the lesion occurs opposite the first or second dorsal vertebræ, the upper extremities may not be at all paralysed, but the lower limbs will be perfectly so, and the respiratory muscles are still affected; but when the lesion is in the part opposite the lumbar vertebræ, only the lower extremities and the bladder are affected.

From these general remarks, it will be seen that the symptoms of inflammatory affections of the cord can only be understood by reference to the physiology of the spinal cord. [NERVOUS SYSTEM, in NAT. HIST. DIV.]

Inflammatory affections of the spinal cord, when independent of accident, are usually fatal; nevertheless, recoveries are sufficiently numerous to justify the medical man in the persevering use of judicious remedies. Cases often occur in which the active disease is arrested, but in which the paralytic affections remain.

In the treatment of this disease, care must be taken not to push antiphlogistic remedies too far. Bleeding is not recommended after paralysis has taken place. At first, purgatives may be had recourse to; but as the case becomes chronic, tonics, and even stimulants, will be borne and found necessary. Counter-irritation over the region of the affected part of the spine should be produced by blisters, &c.; but care must be taken that there is no tendency to gangrene, which is likely to set in in these cases. One great point to be attended to in all these cases is, the state of the bladder. Although urine may be passed, voluntarily or involuntarily, the bladder may nevertheless, from its paralysed condition, remain in a distended state, and if the water is not drawn off by the catheter bad consequences will result. It is also of great importance to keep the patient clean and dry, as if this is not attended to ulceration will occur in the parts with which the urine is in contact, and increase the suffering and danger of the patient.

(Watson, *Lectures on the Principles and Practice of Physic*; Aitkin, *The Science and Practice of Medicine*.)

MYRIAD ($\mu\upsilon\rho\acute{\alpha}\varsigma$), the Greek term for ten thousand; usually employed in our idiom for an indefinite but very large number.

MYRICIN. [BEES' WAX.]

MYRICYL. [BEES' WAX.]

MYRICYLIC ALCOHOL. [BEES' WAX.]

MYRISTIC ACID ($C_{25}H_{47}O_3 + HO$), is a crystalline fatty acid found in the seeds of *Myristica moschata*, the common nutmeg. Combined with glycerin, it forms the fat of the nutmeg; with the oxide of ethyl, a myristic ether which is an oily liquid.

Myristic acid has also been recently found amongst the products of the saponification of spermaceti.

MYRISTICA MOSCHATA. Nutmeg. [MYRISTICA, in NAT. HIST. DIV.] The genuine nutmeg must not be confounded with the Californian nutmeg, the produce of the *Torreya myristica*, a tree native of middle Florida, growing on calcareous hills along the eastern side of the river Appalach, and at Aspalaga.

This is so called not from its spicy qualities, nor from possessing any of the intrinsic properties of the nutmeg, but from its cone bearing a very close resemblance to that fruit, more especially in the runcinated appearance of its seed. See 'Bot. Mag.' pl. 4780; also 'Edinburgh New Philos. Journ.', vol. x., July 1859, p. 7.

MYRISTONE ($C_{26}H_{47}$, $C_{28}H_{47}O_2$?) The ketone of myristic acid. It bears the same relation to myristic acid as acetone does to acetic acid.

MYRONIC ACID. An acid of unknown composition contained along with *myrosin* in black mustard. In contact with myrosin and water it gives essential oil of mustard, or sulphocyanide of allyl. [FERMENT.]

MYROSIN. [MYRONIC ACID.]

MYROSPERIUM. Balsam of Peru, according to Richter, contains two oils, *myroxylon*, which is insoluble in alcohol, and *myrosperrum*, which is soluble in that liquid. The latter substance when treated with an alcoholic solution of potash, yields cinnamic acid and a resinous body.

MYROSPERMUM. Balsam of Peru and of Tolu. All conjectures respecting the sources of these balsams are set at rest. They are not only the produce of trees specifically distinct; but of trees growing in very different countries, that yielding balsam of Peru being the produce of a new species of myrosperrum, described by the late Dr. Royle under the name of *M. pereiræ*. It somewhat resembles the *M. pubescens*, of Kunth. It grows only on the *Balsam Coast*, which is in the neighbourhood of Sonsonate, State of St. Salvador, Guatemala, reaching from the front of Acajutla, to that of Libertad. Thus it seems that none comes from Peru, though the name would imply that it does. Royle's 'Materia Med.', 3rd edition, 1856.

Balsam of Tolu flows from incisions in the tree, and is of the consistence of a strong turpentine. It is sent to Europe in earthenware jars or tin cases. It becomes tenacious with age, and in cold weather may be fractured, but melts again in summer, or with the warmth of the hand. It is of a yellow or brownish colour, transparent, with the taste and odour of the white balsam of Peru. This balsam is much adulterated. All the three forms possess the ordinary qualities of balsamic substances, and, either in the state of syrup or tincture, are employed where such medicines are indicated. These have been already detailed [BALSAMS], and it is only necessary to state here, that their fragrance renders them pleasant adjuncts to cough mixtures,

when the acute or active stage is passed, while the difference of price is the only reason for preferring one kind to another.

MYROXOCARPIN ($C_{18}H_{36}O_6$). A resinous body extracted from the white Balsam of Tolu.

MYROXYLIC ACID. *Carbobenzoic Acid*. An acid obtained from Balsam of Peru. It is probably impure benzoic acid.

MYRRH, *Medical Uses of*. [BALSAMODENDRON, in NAT. HIST. DIV.]

MYSTERIES. [DRAMA; *French Drama*.]

MYSTERY (μυστήριον). In the religion of the Greeks there were rites and doctrines which were kept secret from the mass of the people and only communicated to a chosen few. These things were called *mysteries*. This word has been adopted by the writers of the New Testament, who apply it to things which are kept secret for a time and afterwards revealed, or to things which are kept secret from some persons though they may be revealed to others, or lastly, to things, which, though not kept perfectly secret, are only made known by symbols. Thus the term answers pretty well to the English word *secret*. It is frequently opposed to words which imply *discovery*. Thus the New Testament writers speak of a *mystery revealed* (μυστήριον ἀποκαλυφθέν) or *brought to light* (φωτωθέν) or *made known* (γνωρισθέν). They call the gospel a mystery, as being a system which had formerly been kept secret, but was now revealed to them, and through them to the world (Rom. xvi. 25, 26; 1 Cor. ii. 7-10; Ephes. iii. 9; vi. 19; Coloss. i. 26, 27; ii. 2; iv. 3). So Christ said to his disciples, "To you it is given to know the mysteries of the kingdom of heaven, but to them it is not given" (Matt. xiii. 11; Mark iv. 11; Luke viii. 10), that is, you are permitted to understand those doctrines which are at present kept secret from others. But afterwards they were commanded to proclaim these secrets to the world (Matt. x. 26, 27; xxviii. 19, 20; Mark iv. 22; xvi. 15; 1 Cor. iv. 1). It is also applied to individual facts or doctrines. Thus the admission of the Gentiles to the privileges of the Christian religion is called a mystery, because it had never before been understood by the Jews (Rom. xi. 25; Ephes. iii. 3-5). The fact that the living will undergo a change at the resurrection is also called a mystery (1 Cor. xv. 51). To the same class belongs the only passage in which the word might perhaps be understood to imply something not merely *unknown* but actually *incomprehensible*, namely, 1 Tim. iii. 16, "Great is the mystery of godliness (or religion, εὐσεβείας); God was manifest in the flesh," &c., which means, "Great is the secret which religion discloses—God was manifest in the flesh," &c. In 2 Thess. ii. 7, "the mystery of wickedness" is "wickedness which is already *secretly* at work in the church," and of which the *revelation* is predicted in ver. 8 (τὸ γὰρ μυστήριον ἤδη ἐνεργεῖται τῆς ἀνομίας, . . . καὶ τότε ἀποκαλυφθήσεται ὁ ἄνομος). The word is used in rather a singular way, but still with the same meaning, in 1 Cor. xiv. 2, where it is said of a person who speaks in an unknown tongue, "in the spirit he speaketh mysteries," that is, he communes with God in language unintelligible to those around. We have examples of the use of the word to denote the secret meaning of a figure or symbol in Ephes. v. 2; Rev. i. 20; xvii. 5, 7. This general signification of a *secret* is the only one in which the word mystery is used in the New Testament. In the Septuagint its meaning is the same (Daniel ii. 18, 19, 27, 28, 29, 30, 47; iv. 9). The early ecclesiastical writers applied the word to solemn religious rites, and this is probably the reason why μυστήριον is translated in the Vulgate by *sacramentum*. In modern usage a *mystery* is a doctrine which is incomprehensible by the human understanding, or which appears to involve facts irreconcilable with each other. Thus the doctrine of the Trinity, the union of the divine and human nature in the person of Christ, the consistency of God's perfect foreknowledge and fixed plan of providence with the free-will of man, are spoken of as mysteries. Not that these doctrines are considered as self-contradictory; for if such contradiction be proved, the doctrine is no longer mysterious but impossible. We believe that they can be explained, though our mental powers are not strong enough to explain them. It is worthy of remark that mysteries (in the modern sense) are found in philosophy and natural religion as well as in revealed religion.

MYSTICS, a Christian sect which arose in the 2nd century, and whose principles are probably to be traced to the philosophy of the Christian Platonists of Alexandria, Ammonius Saccas and his followers. They first appear as a distinct sect in the 4th century, under the teaching of a Grecian fanatic, who gave himself out to be Dionysius the Areopagite, one of St. Paul's converts (Acts, xvii. 34), and who is generally regarded as the founder of the sect of the Mystics.

Adopting the Platonic doctrine, that the human soul is a portion of the divine nature, they held that every man has a divine light within him which is sufficient for his guidance to present and future happiness, but that this light is obscured by the grossness of our material bodies and by the influence of external objects. To shake off these evil influences, and thus to keep the soul in as close connection as possible with its divine original, they considered to be the essence of religion; and this they endeavoured to accomplish by constant meditation on spiritual objects, secret communion with God, and an austere discipline of the body. As they considered everything external to the soul as only calculated to obscure the divine light within, they set no value upon accurate systems of doctrine nor upon religious observances as contributing to the advancement of religion. One of their leading doctrines was that real love to God must necessarily be disinterested, that is, uninfluenced by the expectation of reward or punishment.

The austere lives and apparent devotion of the Mystics caused their principles to spread extensively in the Eastern church, and had a great influence in the spread of monachism. In the 9th century they were introduced into the West by a present which the Grecian emperor Michael Balbus made to Louis le Debonnaire, of the works of Dionysius the Areopagite, which however are undoubtedly spurious. The book was translated into Latin by the order of Louis, and the principles contained in it soon found many followers. In the 13th century the Mystics were the most formidable opponents of the schoolmen, and gradually many eminent men who were disgusted with the puerile conceits and lifeless religion of the latter, attached themselves to the Mystics, or rather to the purely spiritual principles held by them; and just before the Reformation, nearly all the friends of spiritual religion were included in this sect. In the 17th century the doctrines of Mysticism were advocated by a Spanish priest, Michael de Molinos, from whose representations of religion, as consisting in the perfect tranquillity of a mind always engaged in communion with God, the sect obtained the new name of *Quietists*. At the end of the same century attention was called to Mysticism in France by the writings of Madame Guyon, whose sentiments were opposed by Bossuet and defended by Fénelon; and in the next century the Pietists of Germany may be reckoned among them. In all these instances, however, it is more a general resemblance in first principles, than any adoption of the tenets either of Ammonius or Dionysius.

MYTHOLOGY (μυθολογία). The mythology of a people may be said to consist of those legends and traditions which have been, at some period or other, usually believed by the majority of the nation, but which cannot be regarded as historical truths on principles of sound criticism. The term therefore, although chiefly referring to them, is not confined to the religious systems of the Pagan nations; it includes everything that has been an object of popular belief, not merely respecting the origin, attributes, and adventures of the gods, but also concerning the early heroes, migrations, and exploits of a people. The historical inquirer has frequently great difficulty in determining at what time the mythology of a nation may be said to cease, and its history to begin; and in fact it is impossible to determine the exact time, since the transition from mythology to history must be necessarily gradual; and many traditions, which appear at first sight entirely mythological, may, upon further examination, be proved to contain some great historical truths.

Though a mythological event may be fictitious, it appears that mythology differs from fiction or fable, in having been once generally believed by a people as an account of events which actually took place. That which is regarded by us as mythological, may therefore be considered by another people as an historical or religious truth; and in the same manner as the exploits and adventures of the gods and heroes in the Mahābhārata and Rāmāyana are viewed by us as mythological, so the exploits and adventures of the Israelites in the conquest of Canaan, in many respects as extraordinary and wonderful as those of the gods and heroes in the great Hindu poems, may be looked upon by the Brahmans as the mythology of the Christian religion.

On few subjects perhaps has more learning been expended, than in investigating the history and origin of the mythology of the principal nations of antiquity. Among the various theories that have been proposed on this subject, the four following appear to have met with the greatest number of supporters:—

1. *The Scriptural theory*, according to which all mythological legends are derived from the facts contained in the narratives of Scripture, though the real facts have been disguised and somewhat altered. The supporters of this theory maintain that all mythic personages may be found in the Scripture; that Deucalion is only another name for Noah, Hercules for Samson, Arion for Jonah, &c. This hypothesis has been supported with a profusion of learned ingenuity and absurdity by Jacob Bryant, in his 'Analysis of Ancient Mythology,' who saw the patriarchs in every minute event of heathen mythology. Sir William Jones, in his dissertations, in the 'Asiatic Researches,' on the Hindu gods, applied Bryant's arguments to the Hindu mythology, though his good sense preserved him to a great extent from the follies which distinguished Bryant's work. Most of the Christian Fathers maintained that the principal deities in the ancient mythology were in reality devils, and that their worship and history had been taught to mankind by the devils themselves. This theory has been adopted by Milton, in the first book of his 'Paradise Lost,' in those lines beginning with—

"First Moloch, horrid king, besmeared with blood
Of human sacrifice, and parents' tears," &c.

2. *The Historical theory*, according to which all the personages mentioned in mythology were once real human beings, and the legends and fabulous traditions relating to them are merely the additions and embellishments of later times. This mode of accounting for the origin of mythology appears to have been in some measure adopted by the Egyptian priests, and was maintained by many of the Greek writers. The Egyptian priests told Herodotus (ii., 144) that their deities originally reigned upon the earth, and that the last who reigned was Orus, the son of Osiris, whom the Greeks called Apollo. An instance of this mode of accounting for the origin of mythology may be seen in the explanation which the Egyptian priests gave to Herodotus of the myth

respecting the foundation of the oracles of Dodona and Ammon, according to which the two black pigeons which came from Thebes, in Egypt, and commanded that the oracles should be established, were in reality two Egyptian priestesses, who had been carried away from Egypt by the Phoenicians, and brought respectively to Dodona and the Libyan desert. Livy also attempts, in a somewhat similar manner, to give an historical explanation of the myth respecting the suckling of Romulus and Remus by a she-wolf (i., 4).

The author of the 'Book of Wisdom' imagines that the heathen deities were originally human beings, and accounts for their becoming objects of religious adoration in the following manner: "For a father afflicted with untimely mourning, when he had made an image of his child soon taken away, now knoweth him as a god, which was then a dead man, and delivered to those that were under him ceremonies and sacrifices.—Whom man could not know in presence, because they dwelt far off, they took the counterfeit of his visage from far, and made an express image of a king, whom they honoured, to the end that by this their forwardness they might flatter him that was absent, as if he were present" (xiv., 15, 17).

Among the Greeks this theory was adopted by Ephorus, and was carried to a great length by Euhemerus, in his 'Sacred History' (*ἱερὰ Ἀναγράφη*), fragments of which have been preserved by Diodorus Siculus and Eusebius. Some of the Christian fathers also adopted this view of mythology, and employed it with considerable success in their controversies with the supporters of the Pagan religion. Among the moderns this theory has been maintained by Banier, in his 'Mythology and Fables explained by History.'

3. *The Allegorical theory*, according to which all the myths of the ancients were allegorical and symbolical, and contained some moral, religious, or philosophical truth, which was originally represented under the form of an allegory, but became, in process of time, to be understood literally. This view of mythology was first introduced into Greece by the Sophists, and an example of it is given by Protagoras in his explanation of the myth of Prometheus. (Plato, *Protagoras*.) In later times this view of mythology was adopted by the New Platonists in their controversies with the Christians; and their object was to show that the ancient mythology, under the garb of allegory, taught all the important duties and doctrines of morality and religion. Thus the view of mythology given by Homer and Hesiod, which was considered by Plato, in his dialogues on the Republic, as mischievous and dangerous, because it attributed human passions and feelings to the gods, occasioned no difficulty with the later Platonists. There is a work of Proclus, of which the curious in such matters may find a translation in the first volume of Taylor's translation of Plato, written for the express purpose of proving, in opposition to Plato, that the mythology of Homer and Hesiod contained nothing contrary to sound principles of morality and religion, since the myths of these poets ought to be understood allegorically.

This method of interpreting the ancient mythology has found much favour among modern writers. It has been adopted by Bacon, in his 'Wisdom of the Ancients;' and has been adopted and carried out to a great extent by Creuzer, in his 'Symbolik und Mythologie der alten Völker, besonders der Griechen,' as well as by Hermann and other recent writers.

4. *The Physical Theory*, according to which the elements, air, fire, water, &c., were originally the objects of religious adoration, and the principal deities were personifications of the powers of nature. Thus the ancient mythology of the Hindus, as developed in the Vedas, personifies the elements and the planets, and differs essentially from the hero worship of later times. The transition from a personification of the elements to the notion of a supernatural being presiding over and governing the different objects of nature was easy and natural; and thus we find in the Greek and Italian mythology that the deities presiding over the sun, the moon, the sea, &c., and not the objects themselves, are the subjects of religious adoration. The Greeks, whose imagination was lively, peopled all nature with invisible beings,

and supposed that every object in nature, from the sun and sea to the smallest fountain and rivulet, was under the care of some particular divinity. Wordsworth, in the fourth book of his 'Excursion,' has beautifully developed this view of Grecian mythology.

Almost all the theories that have been brought forward, either in ancient or modern times, to account for the origin of mythology, may be classed under one of these four divisions; but though all of them are true to a certain extent, not one of them taken by itself is sufficient to account for all the mythological traditions of a nation. But among recent authorities a system has been in a great measure developed which, while borrowing something from each of the systems above noticed, goes deeper than any. It is that which has received the name of Comparative Mythology, and which is correlative with and indeed an integral portion of comparative philology. Like that, finding a close similarity between the myths of widely-dispersed civilised races, it traces the original forms back to an Asiatic, or, as it is termed, Arian source; from whence the Sanskrit on the one hand, and on the other the Greek, Italian, Teutonic, and Slavonic languages and traditions, have alike been derived: the myths, like the dialects, varying more and more as they advanced farther from their parent home, and taking in every instance their actual and characteristic shape and colour from their respective nationalities. The virtual identity or common origin of Greek, Sanskrit, and Teutonic mythology, for instance, has been shown by Grimm and others. The myths themselves are in this system regarded as having arisen primarily from either the simple poetical conception and expression of natural phenomena, from animal symbolism, or from the aggregation of subsequent events and circumstances about historical facts, or the deeds of national heroes—these events being often borrowed from neighbouring tribes or people, as well as those of the nation with which the particular tradition or hero may be identified. But myths, to whatever class they belong, were in fact in constant course of growth and embellishment; and as the additions were made without any very nice regard to probability or aptitude, and merely with a view to this aggrandisement of the national deity or hero, they almost inevitably came in course of time to present a congeries of incongruities, contradictions, and absurdities. The separation of these from the primal myth, and their localisation, are among the essential points to be sought after in order to arrive at the original meaning and purpose of the myth itself, as well as the country in which it originated.

The preceding observations are only intended to give a general view of mythology, and of the principal systems which have been proposed in ancient and modern times to account for its origin. The particular mythology of any nation must be acquired by aid of the articles in other parts of this work, such as BRAHMA, VISHNU, FAIRIES, HERO, GENII, ZEUS, HERA, APOLLO, ARES, &c., and more particularly by the help of such works of reference as are enumerated below.

N

N is one of the liquid or trembling series of letters. It is formed with the tongue at the point where the teeth and palate meet, and the sound passes chiefly through the nasal passage. For the characters by which this letter is represented, see ALPHABET.

The letter *n* is subject to the following changes:—

1. It is interchangeable with *nd*. Thus the Latin roots *men*, *fini*, *gen* (genus), appear in Saxon English as *mind*, *bind* or *bound*, *kind* or *kin*. The converse change is common in the provincial dialect of Somersetshire, where the English words *wind*, *hind* (behind), *find*, *round*, and, are pronounced *wine*, *hine*, *vine*, *roon*, *an*; while on the contrary, *manner* is changed to *mander*. [D.]

2. Before *f*, *n* was silent in Latin. Hence the town *Confluentes*, at the junction of the Moselle and Rhine, is now called *Coblenz*. So the German *fünf* is in English *five*.

3. *N* final often becomes a more complete nasal, and is equivalent to *ng*. Thus the German infinitive in *en* appears to be the parent not only of the participle in *end*, but of the substantive in *ung*, with which are connected the English participle and substantive of the same form in *ing*. The Somersetshire dialect prefers the *n* without *g*, as *stanin*, *sparklin*, *starvin*, for *standing*, *sparkling*, *starving*. The Sanskrit alphabet has a particular character for this sound.

4. *Ni* or *ne* before a vowel often forms but one syllable with that vowel, the *i* or *e* being pronounced like the initial *y*. This sound is represented in Italian and French by *gn*, as *Signor*, *Seigneur*; in Spanish by *ñ*, as *Señor*; and in Portuguese by *nh*, as *Senhor*: all derived from the Latin *senior*, elder.

5. *N* is interchangeable with *l*. Hence the double form of *luncheon* and *nunchion*; but see *L*.

6. *N* with *m*, particularly at the end of words. [M.]

7. *On* and *o* are frequently interchanged. Hence the disappearance of the final *n* in the Latin nominatives *ratio*, *ordo*, *Laco*. The Portuguese also often discard an *n* so placed. It is probably from a confusion between the two sounds that the question has arisen, whether the letter *ain* of the Hebrew alphabet is an *o* or an *n*.

8. *R* final perhaps with *rn*. Hence the double forms of the Latin verbs *cer* and *cern*, separate; *ster* and *stern*, strew; *sper* and *spern*, kick, despise. Again *star* (and the Latin must once have had *stera* in order to form from it the diminutive *stella*, as from *puera* comes *puella*) is in German *stern*. *Spur* in the English is *sporn* in German, and of the same origin perhaps is the name of the *Spurn Head*, at the mouth of the Humber, as well as the Latin *spurn-ere*. The Latin *bur* (seen in *com-bur-o*) is the same word as the English *burn*; and even the Latin *curr-ere*, to run, has in Gothic the form *urn-an*, just as the south-western dialect of England has *hurn*, and the ordinary English, by a slipping of the *r* [R], *run*. In the same south-western dialect *before*, *avaurn*, *orn*, *norn*, *ourn*, are the forms employed for *before*, *afore*, or or either (Germ. *oder*) *nor*, or neither, *our*. It is, however, not improbable that the *n* so often attached to roots ending in *r* is the remnant of an actual suffix, like the *en* or *on* of our *open*, *reckon*, or the *av* of so many Greek verbs, *λαμβάνω* for example.

9. *N* with *s*. This change will not be readily admitted without consideration, as the sounds appear so different. The change however is very parallel to the admitted change of *l* and *d*; and indeed as the two latter letters are formed at the same part of the mouth, so are *n* and *s*. The close connection of the two letters will be most forcibly demonstrated by examples of suffixes in which the change occurs. Thus the English language has a double form of the plural suffix in *en* and *es*, as in *oxen* and *asses*. The Greek verb has the same variety; first, in *τυπτομεν* and *τυπτομες*; secondly, in *τυπτετες*, which must have been the older form of *τυπτετε*, and the so-called dual *τυπτετον*. Again the Latin comparative has for its oldest suffix *ios*, as in *melios*, whence both *melior* and *melius*; or a better example occurs in *ple-ios* and *pleos*, whence the latter forms *plous* and *plūs*. On the other hand the Greek suffix is *ion*, as *πλε-ιον* and *πλεον*, from the same root as the Latin *plus*, and with the same meaning. The old genitive plural suffix in Latin appears to have been *sum*, as *servosum*, whence *servorum*; but the Sanskrit often exhibits plural genitives in *nam*. The suffix for a female in Greek is either *na* or *sa*, as *βασιλιννα*, *μελαινα*, *λεαινα*, or *βασιλισσα*, *τυπτοουσα*; and in English we have *ess*, while the Germans have *inr*. Lastly, such verbs as *σβεν-νυμι* have *σβεν* for the radical part, which often takes the form *σβες*, as *α-σβεσ-τος*; and the same change appears in *σωφρον*, Nom. *σωφρων* and *σωφροσυνη*. As regards *pōno*, *posui*, *positum*, the imperfect tenses are compressed from *pos-n-o* or *pōs-in-o*, so that this is no example of such interchange.

10. *N* before *s* silent, but lengthening the preceding vowel. This fact is well exemplified throughout the grammar of the Greek language. The Latin had the same peculiarity. Hence *consul* was sometimes written *cosol*, and when abbreviated was always represented by the three first of the sounded letters, namely, *cos*. So *censor*, *infans*, *vicies*, *vicesimus*, are often found in the form *cesor*, *infas*, *vicies*,

vicesimus. We see too why the Greeks wrote the Latin word *κηνσωπ* *Κωνσταντινος*, with a long vowel in the first syllable. Lastly, while the Germans write *gans*, *wünschen*, the English have *goose*, *wish*.

11. *N* silent at times before *t* and *th*. The English word *mutton* is derived from the French *mouton* and the Italian *montone*; and our word *tooth* in the older Gothic dialects was *tunth*, thus corresponding as nearly as it ought to do with the Greek *οδοντ*, and Latin *dent*.

12. *N* before *v* silent. Thus the Latin *convention*, assembly, became *covention* (as it occurs in one of the oldest inscriptions), before it was reduced to *contion*, the assembly of the people, a word which most modern editors, in spite of all the best MSS. and of etymology, persist in writing with a *c* for the fourth letter. Similarly from *conventu* came the French *couvent*: and though the English generally say *convent*, yet the name *Covent Garden* is a proof that the *n* was not always pronounced even here.

An initial *n* is either prefixed to, or taken from, words by error. Thus *nadder*, a snake, has now lost its *n* through a confusion of the phrase *a nadder* with *an adder*. On the other hand, the phrase *for then once*, that is, *for this once*, in which the article has its old accusative form *then*, is now written *for the nonce*. It is in this way that we should account for the prefixed *n* in the diminutives *Ned*, *Nol*, *Nan*, *Nel*, for *Edmund* or *Edward*, *Oliver*, *Anne*, *Ellen*, as if the original phrases *mine Ed*, *mine Anne*, had been confounded with *my Ned*, *my Nan*? At any rate, *mine*, *thine*, *an*, were severally the original forms of *my*, *thy*, *a*, and used even before consonants; nay, in Somersetshire they have changed *aunt* to *nânt*, *uncle* to *nuncle*, *awl* to *nawl*. Very similar is the prevailing error of calling the Greek negative particle *alpha privative* instead of *av privative*; the latter of which corresponds so accurately with the Latin *in* and the English *un*, to say nothing of the Greek *aveu*, and the German *ohne*. In fact, *n* at the end of words is often pronounced very faintly.

The Somerset dialect has been referred to because its peculiarities have been recorded with great care in Mr. Jennings's 'Observations.'

NABOB, or NABAB, a corruption of the Hindustani Nuwwab, which was the title of the governor of a province under the Mogul empire, such as the Nuwwab of Arcot, of Oude, &c. (Gilchrist, 'Vocabulary.') Several of these gradually assumed an independent sovereignty during the decline of the empire, and became either allies or dependents of the Anglo-Indian government. The word Nabob is sometimes used in Europe to mean a wealthy man who has made his fortune in India.

NABONASAR, ERA OF. [PERIODS OF REVOLUTION.]

NADIR. [ZENITH.]

NÆVUS (*Nævus maternus*, *Mother Spot* or *Mole*) is a congenital mark or morbid growth on a part of the skin. Nævi are of various kinds; some are merely yellowish or brown discolorations of the skin without any evident alteration in its structure; but the greater number are composed of an excessively vascular tissue, or a dense network of arteries and veins forming a reddish or livid substance, more or less elevated above the surface of the surrounding skin. A third kind are like extensive warty excrescences, and many of them are covered with thick-set coarse hair.

The nævi of the first kind rarely require treatment. Those of the second are more important from their tendency to increase, or to ulcerate and slough, or to produce severe hæmorrhage by the rupture of some of their vessels. Many plans have been suggested for their removal. If they be not seated on an exposed part, or if they do not show a tendency to increase, they had better be left without treatment. In other cases, the simplest and sometimes a sufficient means is the continued application of cold with moderately firm pressure; but a more certain method is to produce such an inflammation in them as may obliterate their vessels and reduce them to the common substance of scars. In small superficial nævi this may be effected by vaccinating them so as to produce a number of pustules on their surface; and in larger ones, by cauterising a part of their surface with fused potash, or nitric acid, or nitrate of silver, or by injecting some stimulant (as dilute nitric acid) into their tissue, or by making small incisions into them, or by passing hare-lip pins and sutures [HARE-LIP] through parts of their substance, or by placing setons in them. The circumstances of each case must decide the choice between these several means, and the mode in which that which is selected may be best applied. Should complete removal be deemed necessary, nævi may be either cut out, or made to slough by tying them round the base. For the third kind of warty nævi, excision is at once the simplest and most secure means.

It is a popular belief that nævi and some other malformations in infants are consequent on an impression made on the mind of the mother during pregnancy, and that the mark always bears some resemblance to the object by which the impression was excited. It cannot be denied, that among the many cases of nævi, some singular coincidences of the kind have occurred, and that in some of these the

malformation might be deemed to have some connection with the object of the mother's fear or anxiety; but till it be determined that the number of these coincidences is greater than would occur according to the common laws of chances (which is as yet far from being proved), the hypothesis of a connection between the state of the mother's mind and the local conformation of the child, which is totally opposed to all physiological probability, cannot be admitted.

NAIADS (*Naiades*, *Nηίδες*) were inferior female deities in the Greek and Roman mythology, who were supposed to preside over rivers, brooks, lakes, and springs: they were in fact the nymphs of the land and fresh-waters, corresponding to the Nereids, or nymphs of the sea. [NEREIDS.] They are represented as young and beautiful nymphs (Hom., 'Od.,' xiii. 103), of whom *Ægle*, according to Virgil, was the most lovely ('Ecl.' vi. 21). By Greek sculptors they were sometimes represented wholly, sometimes only partially draped, and holding large shells. They are frequently figured with Pan; occasionally with Heracles, sometimes with Zeus. *Arethusa*, the fountain-nymph, is represented on the coins of Syracuse. Many of the heroes of the Homeric poems are described as the offspring of Naiads.

According to Pausanias (viii. 4, § 2), the Naiads were called, by the Arcadians, *Dryades* and *Epimeliadæ*. [NYMPHS.]

NAIL MANUFACTURE. Until a comparatively recent period almost every kind of nail was produced by hand-labour; each nail was separately forged from a thin rod of iron, a process which is still followed in the production of what are technically known as *wrought* nails. As nails so formed possess certain advantages, for particular kinds of work, over those formed either by casting, or by cutting or stamping out of rolled sheet metal, there is no reason to anticipate the total abandonment of this process, notwithstanding the continual improvement of nail-making machinery.

The making of wrought nails, which retains, in most places, the character of a domestic manufacture, forms the employment of a peculiar class of blacksmiths called nailors, who are very frequently assisted by the female members of their families. The nailor receives his iron in the form of narrow square rods, of various sizes, according to the kind of nail to be forged from them. Putting the ends of three or four such rods into the forge-fire at once, the nailor commences his work by withdrawing one when it is properly heated, and forging its end upon a small but very firmly bedded steel anvil to a tapering point. The pointed end is then cut off to the proper length, which is adjusted by a gauge, by laying it across a fixed chisel or *hack-iron*, and giving it a smart blow with the hammer. In some cases, as in making the kind of nail used for fixing horseshoes, this operation completes the nail; but in most instances a subsequent process is necessary to form the head. For this purpose the red-hot spike just cut off from the nail-rod is taken up and dropped, point downwards, into one of the holes of an instrument called a *bore*, which is a piece of iron ten or twelve inches long, with a perforated knob of steel at each end. The holes of this instrument are made to fit the upper or thicker part of the nail, and are so countersunk at their upper ends as to form a kind of mould for the head of the nail. When dropped into one of these holes, a few well-directed strokes of the hammer upon the thick projecting end of the spike or nail converts it into a head of any required shape. In making small nails it is sometimes practicable to forge and cut off two lengths from the nail-rod with one heating; but where this is not the case the nailor is enabled to proceed with his work without interruption by the convenient plan of having several rods in the fire at once, so that as soon as one is cool another is ready to his hand. In many cases, for the sake of economy, two or three nailors work at one hearth, using the same fire and the same bellows in turn; and some hearths have been constructed large enough for five or six men. The hammer used by nailors is larger or smaller, according to the size of the nails to be formed; and its face is inclined considerably upwards towards the handle. Some of the nailors acquire remarkable dexterity. One of them, a few years ago, made 34,000 flooring nails in a fortnight; in performing this task, as each nail required about twenty-five strokes of the hammer, he made, including the cutting up of the nail-rods into convenient lengths, and re-uniting them when they became too short, no less than 1,033,656 strokes, and moved to and from the fire at which the rods were heated 42,836 times.

For some purposes nails formed by the much cheaper process of casting have been long used instead of those wrought in the manner above described. Common cast nails are, however, so clumsy and so brittle that they can only be used for a few coarse purposes, as in plasterer's work, and in the nailing up of fruit-trees. By the introduction of great improvements in the manufacture, however, a very useful kind of cast nail, of an exceedingly pure material called malleable cast iron, has been successfully introduced for certain descriptions of woodwork. Nails of this kind are very neat and regular in their appearance, being cast with great accuracy; and they are annealed to such perfection that the metal will bear far more bending than ordinary wrought-iron without injury. This extraordinary degree of tenacity is, however, obtained at the expense of rigidity, such nails being often nearly as soft as copper, and therefore quite unsuitable for use in hard woods.

The comparatively high price of wrought nails, owing to the great amount of manual labour required in making them, and the insufficiency of cast nails as a substitute for them, has led to the introduction

of many highly ingenious machines for forming nails by cutting, stamping, or compression, out of plates or rods of rolled iron; and with such success that, for the ordinary purposes of the carpenter and joiner, cut-nails, varying in size from the smallest tack or brad up to spikes of six inches or more in length, have almost superseded those wrought by hand. The earliest machine for nail-making was that contrived by Mr. French, of Wimborne, Staffordshire, in 1790, in which no material departure was made from the ordinary process of making nails by the hammer; but labour was saved by working hammers by water-power, so that women and children might perform work which would otherwise have required men. The Americans, so long as the year 1810, possessed a machine which performed the cutting and heading at one operation, with sufficient rapidity to turn out more than 100 nails per minute. In the process now most commonly followed, nails are cut from sheet-iron of suitable thickness.

Fig. 1.—Cutting sheets of iron for nails.

The sheet is reduced, by cutting transversely, into strips or ribands of a breadth equal to the intended length of the nails. These strips are then applied to a machine in which a chisel-shaped cutter descends with sufficient force to cut off from the end of the strip, at each down-

Fig. 2.—Making cut brads.

ward stroke, a narrow piece sufficient to form one nail. As the nails are required to be of a tapering form, the cutter must be so fixed as to

present a slightly oblique angle to the direction in which the strip is pushed into the machine; and this obliquity must be reversed or varied after each stroke, by means similar to those adopted in comb-cutting machinery. If the nails are to be of any of the kinds to which the term *nail* is specifically applied, as distinguished from *brad*, the action of the cutter is simply reversed, so as to reduce the strip of iron into long wedge-shaped pieces; and the pieces thus separated are subsequently headed by pressure or stamping, so as to form finished nails; but if the nails are to be of the *brad* kind, the action of the cutters must be so modified as to produce cuts alternately at right and oblique angles with the edges of the strip. Nails of this kind need no subsequent heading, but are completed by the action of the cutter. In some machines the cutters do not vibrate or vary their position, but the strip of iron is turned after each cut, so as to produce the same effect. Brads are frequently cut out of hoop-iron instead of transverse strips of sheet-iron, as above described.

Many of the machines recently invented effect improvements in the manufacture of cut nails; while others, intended for wrought nails, are also applicable to the making of bolts, rivets, spikes, nuts, and screw-blanks. The obvious mode of manufacturing these in a rough way is to forge the heated end of an iron rod, and to fashion the metal with the hammer; but the machines now employed increase both the accuracy and the rapidity of the manufacture. One of these machines, invented by Mr. Marrow, of Sheerness Dockyard, is so contrived that it may be put in action by means of a pulley placed upon any moving shaft whatever, whether driven by steam or other power. There are hammers, tappets, &c., connected with the forging part of the mechanism. With one of these machines one man can make sixty half-inch bolts, an inch and a half long, with hexagonal heads, per hour. Mr. Grice's machine, of recent introduction, forms a head on the heated end of an iron rod, converting the rod into a bolt, rivet, spike, or screw-blank. The rod is placed, heated end uppermost, in a die, and by the motion of a bed the rod is brought under a heading-machine, which fashions the head by a pair of dies; another apparatus liberates the bolt or spike; and provision is made for keeping the dies cool by allowing a stream of water to fall on them. Mr. Ward's machine, also introduced within a year or two, is so contrived as to make two bolts or other articles by one revolution of a driving shaft. The machine is fed with iron rods by an attendant; and the metal, whether hot or cold, is cut off and then shaped by dies. There are many other bolt-making machines now in use, some of which fashion the bolt or rivet while in a vertical position, others while horizontal; but it is not necessary to describe them separately. The expediency of making rivets by machinery has now become manifest, since modern engineering, exhibited in such works as the Britannia Bridge and the *Great Eastern* steam-ship, requires rivets by millions at a time. Of the new patents for cut-nails, such as Bowman's, Coates's, Goose's, Poole's, Frearson's, and others, it may be said generally that they relate to minor improvements of some of the processes already described in this article.

Birmingham and its neighbourhood are the great seat of the nail manufacture; wrought nails being made in the villages round about, while cut nails, as well as machine-made bolts, rivets, and spikes, are produced in large factories wrought by steam-power. There are establishments in Birmingham which produce 40,000,000 cut nails per week each,—enough in a year to encompass the earth if placed end to end. A few years ago it was estimated that 25,000 persons were employed in the manufacture; and that 6000 tons of nails were exported, after supplying the home trade.

NAMES. [NOUN.]

NAMES, PROPER, are words by which single objects are denoted, as countries, rivers, towns, men, &c.

But when we speak of proper names, we mean, more usually, the names of men; and on this subject, to which little attention has hitherto been paid, and especially such proper names as appear among ourselves, it is our intention to offer a few observations.

In the primitive state of society, as soon as men were so far advanced as to find the convenience of having a verbal denotation of the individuals who composed a tribe, the rule would undoubtedly be, "one man, one word." we see this to be the case in the uncivilised tribes; and as man is presented to us in very early historic periods, we still see the same system prevailing. In the Hebrew genealogies, we find a single word, as *Terah*, *Abraham*, *Reuben*, *Aaron*, *David*, *Solomon*, the only designation of the persons whom those words call up before us; and if in any instance there is any deviation from the rule, it is for some special reason, and we see it to be an exception to what was the usual practice.

In the other nations, the fathers of European civilisation, it was the same; Egypt, Syria, Persia, and Greece; one person, one word: and so in the earliest periods to which we can ascend in the history of the Latin nation, we have rarely more than one word to denote one individual, or if there is a second word employed, it bespeaks an origin in something which is apart from the simple, colloquial, and usual designation of him.

In the Celtic and German nations it appears to have been the same; *Arminius*, *Ariovistus*, and the like: and in Britain, *Caractacus*, or *Caradoc*. The Saxons were a nation in whom this, the primitive system, was still prevalent, not only when they first established a

colony in Britain, but during the whole period that they held the supreme authority in this island. Persons do, to be sure, present themselves in the pages of historians with such additions as *Harefoot*, *Iron-side*, but it may be reasonably doubted whether these terms can be properly regarded as names; and if it is admitted that they may be such, still these are only exceptions, the great mass of the Saxon population, of whatever rank, having but one single word by which the individual was denoted, such as *Edwin*, *Alfred*, *Gurth*, *Ulf*, *Tosti*, *Harold*, and the like.

As nations advanced in refinement, the names of the individuals comprising them became more complex. Amongst the Romans, for instance, we have *Publius Cornelius Scipio Africanus*, *Caius Julius Caesar*, *Publius Ovidius Naso*; and names of this class formed the rule, at least in families which were free. The slaves probably remained with the single word only.

We have not room to enter into an examination of the principle on which this new form of personal denomination was constructed. A uniform principle, like that very valuable one on which our own personal nomenclature is at present constructed, perhaps did not exist, so that our present system is rather to be regarded as the invention of modern nations, than as borrowed by them from any of the nations of more ancient civilisation.

The principle of the modern system of personal nomenclature in our own nation is this: to have one name for the individual, joined to a second name, which is common to some particular stirps in the great English family to which he belongs. We call the two the *name* and the *surname*. We think in these days much more of the latter than of the former. But in the more solemn acts of our lives, we find the proper consequence given to that which is indeed the name; in baptism, in elementary Christian instruction, at marriage, when the name is the thing in question, it is that which is properly the name, and not the surname, which is pronounced; *John*, *Richard*, *Anne*. We may find in books, even down to the close of the 17th century, that catalogues and indexes are sometimes so constructed, that the names, and not the surnames, are ranged in alphabetical order. Philips's '*Theatrum Poetarum*' presents a late instance.

The value of this principle lies here: that it is a simple and easy mode of showing, to some extent, to what family an individual belongs; it promotes family union; but its chief advantage lies in the facilities which it affords for conducting inquiries into the condition of the ancestors of persons who may feel any curiosity on the subject, which, without the indications afforded by identity of surname, could be attended with very little success, when it was attempted to ascend beyond the recollections of persons still living.

This mode of designation, we believe, prevails in most other countries of modern Europe. In England it is almost the universal plan. The royal house of England forms an exception, an unchangeable surname having never been adopted by them. In this respect the house of Brunswick is like the houses of Saxe, Nassau, Bourbon, Orleans, and a few others, springing from the persons who were of prime note in that state of society when the rule was, "one person, one word," and being afterwards too conspicuous by rank and station to need any such ordinary mode of distinction as that which the adoption of an invariable addition to the name would have given them. This was once not peculiar to the royal house of England in this island (the Stuarts, it may be observed, and perhaps the Tudors, but not the Plantagenets, were a temporary exception, being families of inferior rank, who were raised by circumstances to the possession of the regal dignity), for the earls, in the first two or three centuries, seem also to have disdained a practice which assimilated them too nearly to the classes next below them. Thus the persons distinguished in Domesday Book as *Comites*, are *Comes Hugo*, *Comes Rogerus*; and never, we believe, with names of addition which descended to their posterity. But all these great houses have become long ago extinct.

There is also an exception to the modern rule, of another kind. There are still some remote and rudely-cultivated districts, in which the inhabitants are better known by some *by name*, as of the house in which they live, or as the son of some person well-known, than by any unvarying addition to their name properly so called. This is said still (or at least no great while since) to be the case in some parts of Yorkshire and Lancashire, and is certainly the case in parts of Wales, but it is probable that the extension of education will bring all parts of this island into subjugation to a plan which has such obvious convenience.

If it is inquired when the system on which we now proceed was first adopted, the fact which has just been stated, that even now the system is not universally prevalent, will show, what is indeed the fact, that, like many other things, it has made its way by degrees. There is not, we believe, a single instance before the Conquest of persons in genealogical succession bearing the same surname; and it is also quite certain that in the mass of the population of England after the Conquest, the descendants of the Saxon population, there can rarely, if ever, be shown an instance of successive individuals of the same family being distinguished by the same surname in the two centuries immediately succeeding the Conquest. We have indeed but imperfect means of pursuing the inquiry for those two centuries. The names of the people of those centuries lie buried in unprinted records and chartularies. But if there are exceptions, and Saxon families in these centuries to be traced using an invariable as well as a variable name, it is in that

remarkable class, who still exist in no very small number, who have one of the old Saxon appellatives in the place of the surname, such as *Thorold, Swaine, Aldred, Thoroughgood* (Turgot), *Godwin*, and the like.

But we find in Domesday Book that several of the Normans and other people from the Continent, who became settled in England at the Conquest, and soon after that event, are distinguished by names of addition, which are not merely personal, but names which were borne by themselves and their posterity after them. Such are *Darcy, Arundel, Devereux, Balliol, Burun, Laci, Perci*, and others, people just below the rank of the comites, and who, gaining great possessions and great power, were afterwards very conspicuous in English history. These are the persons, we conceive, who first set the example of the practice which has since become all but universal among us.

The disposition which always more or less exists to imitate what is done by a superior, is probably the principle to which we are to refer the change in this point which we find to have taken place by the middle of the 14th century.

By that time the present system may be said to have been pretty generally established in all the well-settled portions of the island. The statute of additions of the 1st Henry V., by requiring that the name and description of the party should be exactly set forth in any writ or indenture, would do something to consolidate the system; and when it was required that in all parishes a register should be kept of baptisms, marriages, and burials, which was one of the acts of the Reformers, there was a new check presented to any attempts at relaxation in the practice.

But even at the beginning of the 15th century there was much that was unsettled in the personal nomenclature of England, even in families to whom pertained portions of the soil. Thus in 1406 a person describes himself as *Willielmus filius Adæ Emmotson*, who in 1416 is *Willielmus Emmotson*; and more remarkably about the same time, a person who is described as *Johannes filius Willielmi filii Johannis de Hunshelf* appears soon after as *Johannes Wilson*. About the same time we had *Willielmus Johnson Wilkinson, Willielmus Adamson Magotson*, and *Thomas Henson Magot*, showing the present system then in its rudiments.

As the system at present existing made its way by degrees, and with much of casualty, so there seems to have been much also of accident in respect of the name of addition which marked the distinction of the stirpes. There are some of the surnames in common use among us for the adoption of which it is difficult now to assign any satisfactory reason. This is partly to be attributed to the corruption which many names have undergone, and partly to the strange additions which we find in the place of surnames in early documents of undoubted authenticity. One of these is *Adam that God made*, whose addition, if he lived at the period when his race first began to conform themselves to the system, would appear now in some form which would probably foil the sagacity of the most skilful inquirer. Sometimes there is a difficulty arising out of a wrong apprehension of the origin. Thus we have the names *Spring, Summer, Winter*; there is no *Autumn*. It is difficult to conceive how the names of the seasons should become the names of families; but in fact it is not so, *Spring* being a word denoting a small grove of trees, so that the name classes with *Wood, Holt*, and others concerning which there is no difficulty; while *Summer* and *Winter* are *Summoner* and *Vintner*, names derived from occupations.

But the great mass of our surnames may be easily explained. We cannot enter here at large into the subject; but it may be useful to those who are inclined to prosecute it, to say that nearly the whole of them may be referred to one of the five following classes:—

1. Foreign names brought in by settlers from other countries, including the Scotch and Irish names. These designate a very large section of the whole population; and there is a constant accession being made to them by the tide of population setting towards England. Very few of the names of this class introduced in the early periods remain: the great majority being of families who have become settled in England in the course of the last century and a half.

2. Names of locality.—These are divisible into two great portions: those which are derived from places of generic names only, such as *Hill, Dale, Cliff, Slack, Combe, Grove, Shaw, Frith*, and many others, mostly monosyllabic, which would originally appear as *John de la Hill*, &c.; and those which are derived from some specific place, as *Atherton, Burton, Denby*, and thousands of others, there being scarcely a town, village, or hamlet which has not given its name to some English family.

3. Names of occupation.—Of this class the number is very great. We have *Brewer, Barber, Smith, Mason*, in short every trade and every other occupation in which men engage. Lost trades or trades which have changed their names are preserved in the names of families whose ancestor was engaged in them at the time when his family fell into the system. Thus we have *Fletcher, Girdler, Furbisher, Stringfellow, Lister, Walker, Pargiter, Webster, Taverner*, and the like. We have also *Palliser, Lander, Foster, Palfreyman, Page, Woodruffe, Reeve, Hunter*, which were evidently at the beginning names of occupation. It is difficult to account for such names as *Bishop, Baron, Earl, Lord, Priest, King*.

4. A large portion of our personal nomenclature is made up of surnames which are formed upon those which we call Christian names.

Nearly all these appeared originally in the form of *Filius*, &c., as John son of William. This mode of designation has taken various forms. Thus on this name of *William*, there are founded *Williams, Williamson, Wills, Wilson, Wilks, Wilkins, Wilkinson, Willis, Willison, Bill, Bilson, Willet, Willimot, Willmot, Till, Tilly, Tillot, Tilson, Tillotson, Willy*, each of which, if written by a scribe of the middle ages in Latin, would be expressed by the same phrase *Filius Willielmi*. Other names have an equally numerous progeny. To this class may be referred *Ives* and *Iveson* which are *Filius Judei*; *Clarkson, Cookson, Wrightson*, which are names formed not indeed on the name, but the profession of the parents.

It would however be to extend this article to an inordinate length, even to touch upon the subordinate classes to the five great classes.

5. The fifth and last is that of names which indicate something peculiar in the personal appearance or mental qualities of the person to whom they are first given. Such are *Swift, Long, White, Black, Crump, Rouse, Wise, Good*, &c.

The names of the ancient Saxon population of England were nearly all descriptive of some quality of mind or body. Thus *Edward* is truth-keeper; *Winfred*, win-peace; *Alfred*, all-peace; *Edmund*, truth-mouth; *Ailwin*, of all beloved; *Ulf*, wolf. But a great change took place soon after the Conquest. We see in the names of the Normans who became settled in England many which continued for ages favourite names of the English nation; *Roger, Ralph, Hugh, Humphrey, Jeffrey, Gilbert*. To them also we owe the introduction amongst us of names of religion. If these names existed at all in England before the Conquest, they were exceedingly rare. In the catalogues of Saxon bishops, not one occurs. Even amongst the first race of Normans they did not abound. We find *Adam, John, Stephen, David, Peter, Matthew*, and perhaps a few others. But in the century and a half after that event, names of this class began to prevail in a great degree. It was a period of extraordinary Christian devotion: the exertions in founding monasteries, building churches, and maintaining the war against the infidels show it. In this state of the public mind the new system of taking names of religion spread and strengthened. The names of religion were almost wholly from the Old and New Testament, a few only being taken from the names of persons who have been eminent in later times for their Christian virtues.

Since then little change has taken place. A few names once common have lost their popularity; a few others have been introduced. There have been periods when names somewhat fantastic have had a popularity; such as the names of the virtues, as *Patience, Truth, Prudence, Faith*, by which women have been named; *Thankful, Faithful, Sabbath*, and others more extraordinary, have been given to men. Some went for a time into another extreme, and we had *Hannibal, Scipio, Cæsar, Hercules*.

We have however not been sufficiently attentive to the importance of keeping up a stock of what we call Christian names. Our population has increased to a very great extent, while our surnames have rather diminished than the contrary. We should therefore, if we wish that names should be what they are intended to be, *Notamina*, increase the number of those names out of which we have the power ourselves of selection. As it is, with a population of 30 millions, we have but 53 names of men which can be used without some appearance of singularity. Of these 12 are in more frequent use than the rest:—

John	William	Henry	George	James	Robert
Thomas	Francis	Charles	Edward	Richard	Samuel

Of these, 4 are names of religion; 4 are names introduced at the Conquest; 3 names introduced at a later period from the nomenclature of other countries; 1 is pure Saxon. Of the 41 names of secondary frequency, 28 are names of religion; so that of the 53 names of men in ordinary use, 32 are names of religion, or considerably more than one-half, and they are all taken from the Scriptures.

Again, looking at the 53 names in respect of the languages from which they are derived, it appears that

25 are of Hebrew origin,
19 from the various dialects of Western Europe,
5 from the Greek, and
4 from the Latin.

There are a multitude of names, once in use in England, which might easily be revived, and it would be a matter of some public convenience to do so. Few persons have not found inconvenience in some form or other from the want of sufficient distinctness in the name he bears. Thus a little time ago there were two antiquarian Chalmers; two Parkes upon the bench; two Whitakers, both clergymen, and both writers on Lancashire topography: some time ago there were two Dr. John Thomas's, both chaplains to the king, and both bishops; and two Dr. Grays, both divines, both writers in their own profession, both connected with historic literature and poetry, and both engaged in controversies with Warburton. This occasions confusion. To change a surname is a difficult and expensive process; the cheapest and simplest remedy is to give a name at baptism which will be marked and remembered, as *Basil Hall*. Of neglected names there are, *Austin, Allan, Aubrey, Arnold, Baldwin, Blase, Barnard*,

Fabian, Ferdinand, Josceline, Miles, Sylvester, Theobald, Theodore, and a host of others.

Some further information of a curious nature will be found in an 'Essay on Surnames,' by M. A. Lower.

NANKEEN, a kind of cotton cloth, usually of a yellow colour, imported from China, and taking its name from the city of Nankin, in which great quantities are made. The peculiar colour is natural to the cotton-wool of which the nankeen is made, and not the effect of any dye. White cloth of similar texture is imported from China; and this, to distinguish it from the yellow kind, is called white nankeen. Nankeen cloth was formerly very much used in England for gentlemen's summer clothing; but better fabrics of home manufacture being now procurable at lower prices, these have taken the place of the Chinese goods.

NAPHTHA. The word naphtha is derived from the oriental term *nafata*, signifying to ooze out, and was originally applied to a yellowish-white, volatile, inflammable, liquid hydrocarbon, which exudes from the soil in certain parts of Persia, Italy, &c. The very fluid portions of those natural tar-like matters [ASPHALT; BITUMEN; PETROLEUM] that issue from the ground in so many parts of the world, having been found to be almost identical with the original *nafata*, have been included under the term naphtha, and the latter word is therefore, or rather should be, now used to designate any light, more or less colourless, inflammable fluid, of mineral origin and immiscible with water. Naphtha is sometimes specifically termed *mineral naphtha*.

Other liquids, resembling true naphtha in little else than the characters of volatility and inflammability, have also been called naphtha. Thus wood-spirit has frequently been so named, and is still often spoken of as *wood-naphtha*; see METHYL, *hydrated oxide of*. ACETONE is also sometimes described under the name of naphtha. Lastly, COAL TAR yields by distillation a liquid having all the characters of natural naphtha; it is, however, generally distinguished as *coal naphtha*.

The origin of naphtha is, in all probability, due to the action of internal heat upon beds of coal or peat, these substances being, in nearly all cases, found in the neighbourhood of the petroleum or naphtha springs; moreover, the artificial production of coal naphtha, as just described, gives considerable support to this theory.

Crude naphtha is usually contaminated with much colouring matter, but from this it may be freed by rectification. When quite pure it contains no oxygen, and hence is usually the liquid in which potassium, sodium, and other metals that have intense affinity for oxygen are preserved. For the latter purpose it must be several times well agitated with about a fifth of its bulk of strong sulphuric acid, then washed with water, and finally distilled from quicklime.

Pure naphtha is colourless, and of peculiar taste and odour. It is insoluble in water; soluble in about eight parts of alcohol; and miscible in all proportions with ether, and with the essential oils. With the aid of heat it dissolves one-fourteenth of its weight of phosphorus, or one-twelfth of sulphur, but deposits them on cooling. It dissolves one-eighth of its weight of iodine, absorbs ammoniacal and hydrochloric acid gases, is attacked by chlorine and bromine, and decomposed by hot concentrated nitric or sulphuric acids. It is an excellent solvent for gutta serena, india-rubber, camphor, and oily or resinous bodies generally; is indeed largely used for these purposes, but chiefly in lamps as a source of artificial light. Its specific gravity varies from 0.7 to 0.85.

Naphtha seems to be a mixture of several polymeric hydrocarbons. Pelletier and Walter have extracted and described three, namely, *naphtha* ($C_{14}H_{12}$), boiling point 190° ; *naphthene* ($C_{10}H_{10}$), boiling point 239° ; and *naphthole* ($C_{24}H_{22}$), boiling point 374° .

Great care should be observed in manipulating with the more volatile descriptions of naphtha. It is exceedingly inflammable, and fatal accidents have arisen from its vapour catching fire on the approach of a naked flame.

For the chief localities of the naphtha springs, and statistics concerning their products, see NAPHTHA, in NAT. HIST. DIV.

NAPHTHALAMIDE. [NAPHTHALIC GROUP.]

NAPHTHALASE. [NAPHTHALIC GROUP.]

NAPHTHALENE. [NAPHTHALIC GROUP.]

NAPHTHALIC ACID. [NAPHTHALIC GROUP.]

NAPHTHALIC GROUP, a division of the Benzoic series of organic compounds. It is chiefly composed of the derivatives of naphthalin.

Naphthalin ($C_{20}H_{18}$), or *hydride of naphthyl* ($C_{20}H_{17}$, H), or *naphthalene*, was first discovered by Garden in coal tar. Faraday determined its composition, and Laurent has particularly investigated its constitution. It is a very common product of the decomposition of organic bodies by heat, but its most abundant source is coal-tar. Large quantities of it are produced at all gas-works, and its separation from the tar may be accomplished by the following process:—After exposure to air for some time the tar is redistilled; the first portion of the distillate is set aside, the second portion furnishes much naphthalin if artificially cooled, but the last portion comes over in an almost semi-solid state, and on standing for a short time sets into a solid mass of crystals of naphthalin. Much oily matter is got rid of on submitting the mass to pressure, and the naphtha is finally obtained in a pure state by successive sublimations or recrystallisations from alcohol.

Naphthalin is colourless, has a somewhat tarry odour, and a burning aromatic taste. It crystallises in large, thin, rhombic plates of pearly

lustre, and unctuous feel. Exposed to light under a glass covering, it gradually sublimes in magnificent crystals, and altogether presents a very beautiful appearance. It fuses when heated to 174° Fahr., and boils at 428° . Its vapour density is 4.582. It is not very inflammable, and when ignited gives off much smoke. It is very volatile in vapour of water. It is insoluble in cold water, very slightly soluble in hot water, but readily so in alcohol, ether, and the fixed and essential oils. It appears also to be soluble in acetic or oxalic acids, but is not acted upon by caustic potash.

Sulphuric derivatives of Naphthalin.

Sulphonaphthalic acid ($C_{20}H_8S_2O_6 + 2Aq.$). *Naphthyl-sulphurous acid*, *hyposulphonaphthalic acid*, or *naphthyl-dithionic acid*. Obtained by acting upon naphthalin with excess of sulphuric acid at a temperature not exceeding 200° Fahr.; it crystallises on cooling. It is very soluble in water, alcohol, and oils, but only slightly so in ether. It has an acid, astringent, metallic taste, and at a high temperature is decomposed. The *sulphonaphthalates* are monobasic; those of the alkalis are readily obtained in crystals. By substitution processes, the following compounds of sulphonaphthalic acid are easily produced; they all form salts with bases, several of the compounds being crystalline:—

Chlor-sulphonaphthalic acid	$C_{20}H_7ClS_2O_6$
Brom-sulphonaphthalic acid	$C_{20}H_7BrS_2O_6$
Bichlor-sulphonaphthalic acid	$C_{20}H_6Cl_2S_2O_6$
Bibrom-sulphonaphthalic acid	$C_{20}H_6Br_2S_2O_6$
Trichlor-sulphonaphthalic acid	$C_{20}H_5Cl_3S_2O_6$
Quadrichlor-sulphonaphthalic acid	$C_{20}H_4Cl_4S_2O_6$
Nitro-sulphonaphthal(or theo)ic acid	$C_{20}H_7(NO_2)S_2O_6$
Binitro-sulphonaphthalic acid	$C_{20}H_6(NO_2)_2S_2O_6$

Disulphonaphthalic acid ($C_{20}H_8S_4O_{12}$). *Thionaphthic acid*, or *hyposulphonaphthinic acid*. This acid is produced under circumstances similar to those under which sulphonaphthalic acid is obtained, but at a higher temperature; fuming sulphuric acid also facilitates the reaction. It is dibasic. Both it and its salts crystallise with difficulty.

Sulphonaphthalin ($C_{40}H_{14}S_2O_4 = C_{20}H_8 + HO, SO_3 - 2HO$). Produced when vapours of anhydrous sulphuric acid are passed into fused naphthalin, the latter being kept in excess. It is a granular body, slightly soluble in water, but more so in alcohol. It is sometimes accompanied by *sulphoglutinic acid* (hyposulphoglutinic acid).

Nitro-derivatives of Naphthalin.

Nitronaphthalin ($C_{20}H_7(NO_2)$). *Nitronaphthalase*. Naphthalin is well stirred with five times its weight of cold nitric acid of sp. gr. 1.33. After some days it is found converted into a lemon-yellow mass of nitronaphthalin, insoluble in water, but soluble in hot alcohol or ether, the solutions depositing it in brittle needles on cooling. Heated with lime, it disengages ammonia, and, among other products, yields a substance called by Laurent *naphthalase*, or, better, *naphthase*.

Binitronaphthalin ($C_{20}H_6(NO_2)_2$). *Nitronaphthalese*. Naphthalin added to hot strong nitric acid is converted into the above compound, which crystallises out on cooling in pale yellow needles. It is only slightly soluble in alcohol or ether. Boiled with alcoholic solution of potash, ammonia is disengaged, and nitric acid then precipitates, from the solution, dark brown flocks of *nitronaphthalesic acid*.

Bromo-binitronaphthalin ($C_{20}H_5Br(NO_2)_2$). A crystalline body formed on dissolving bibromonaphthalin in nitric acid.

Trinitronaphthalin ($C_{20}H_5(NO_2)_3$). *Nitronaphthalise*. This compound occurs under three isomeric modifications. It is obtained on boiling naphthalin for some days in nitric acid. It is colourless, and crystallises in irregular tables or prisms. Alkalies colour it red.

The final product of the prolonged action of nitric acid upon naphthalin is a mixture of oxalic and phthalic acids, thus:—

Phthalic acid ($C_{16}H_6O_6 = 2HO, C_{16}H_4O_6$). *Naphthalic acid*. *Alizaric acid*. In addition to the method just mentioned, this acid results from the long-continued action of nitric acid upon bichloride of naphthalin, alizarin, or purpurin. [MADDER, COLOURING MATTERS OF.] It may be obtained in the pure state by repeated crystallisation from water, and then forms lamellar groups. It is very soluble in alcohol or ether. By distillation with lime it is converted into carbonic acid and BENZOLE, and when heated alone it sublimes in beautiful elastic needles of *phthalic anhydride* ($C_{16}H_4O_6$), called also *anhydrous phthalic acid*, and *pyroalizaric acid*. It is a bibasic acid, and forms neutral and acid *phthalates*.

Trichlorophthalic acid ($C_{16}H_3Cl_3O_6$), *chlorophthalic acid* is produced by the action of nitric acid upon sexchloronaphthalin.

Nitrophthalic acid ($C_{16}H_5(NO_2)O_6$) may be obtained in yellowish rhomboidal crystals by evaporation of the mother liquors from the preparation of the nitronaphthalins. It is bibasic, and forms crystalline salts. By sublimation it is reduced to the anhydrous condition.

Phthalamic acid, or *naphthalamide phthalamide* ($C_{16}H_7NO_6$), results from the action of ammonia upon anhydrous phthalic acid.

Phthalimide, or *naphthalimide* ($C_{16}H_5NO_2$), sublimes in thin plates when acid phthalate of ammonia is heated. It is colourless, almost insoluble in water, but readily soluble in boiling alcohol or ether.

Phenyl-phthalimide, or *phthalanile* ($C_{28}H_9NO_4$), is produced by the action of aniline upon ammonia. *Phenyl-phthalamic acid*, or *phthalanilic acid*, contains ($C_{28}H_{11}NO_6 = C_{16}H_9(C_{12}H_5)NO_6$).

Chlorine and Bromine derivatives of Naphthalin.

These are extremely numerous, and are of two kinds. First, those which are simply naphthalins ($C_{20}H_8$), in which an atom or atoms of hydrogen are replaced by equal quantities of chlorine or of bromine. The following is a list of them:—

Chlor-naphthalin (chlonaftase)	$C_{20}H_7Cl$
Brom-naphthalin (bronapftase)	$C_{20}H_7Br$
Bichlor-naphthalin (chlonaftese)	$C_{20}H_6Cl_2$
Bibrom-naphthalin (bronapftese)	$C_{20}H_6Br_2$
Trichlor-naphthalin (chlonaftise)	$C_{20}H_5Cl_3$
Tribrom-naphthalin (bronapftise)	$C_{20}H_5Br_3$
Bromo-bichlor-naphthalin (chlorebronapftise)	$C_{20}H_5Cl_2Br$
Quadrachlor-naphthalin (chlonaftose)	$C_{20}H_4Cl_4$
Bromo-trichlor-naphthalin (chloribronapftose)	$C_{20}H_4Cl_3Br$
Bibromo-bichlor-naphthalin (chlorebronapftose)	$C_{20}H_4Cl_2Br_2$
Quadribrom-naphthalin (bronapftose)	$C_{20}H_4Br_4$
Bibrom-trichlor-naphthalin (bromechlonaftuse)	$C_{20}H_3Cl_3Br_2$
Sexchlor-naphthalin (chlonaftalase)	$C_{20}H_2Cl_6$
Perchlor-naphthalin (chlonaftalise)	$C_{20}Cl_8$

Several of the above compounds exist in seven, or less, distinct modifications; Laurent, the completeness of whose researches on these bodies is only equalled by their importance, accounts for this fact by supposing that each of the eight equivalents of hydrogen in naphthalin has its allotted position, and that according as one or other is replaced by the chlorine or the bromine so do the properties of the resulting compound differ.

In naming the many derivatives of naphthalin, Laurent adopted the word *naphth* as the root, prefixing it by *chlo*, *bro*, &c., to indicate the substituting element; and introducing the vowels, *a*, *e*, *i*, *o*, *u*, when it was necessary to show that one, two, three, four, or five atoms of the element had been taken into the compound molecule. When more than five replacing atoms were employed, the syllable *al* was introduced, and the use of the vowels recommenced. Numerous examples of this useful, though scarcely euphonical, nomenclature will be observed throughout the article.

The second class of chlorine and bromine derivatives of naphthalin are combinations of the compounds just described, with additional equivalents of chlorine or bromine, ordinary *chlorides* and *bromides* resulting. They are nearly all formed by the direct action of chlorine or bromine upon the different naphthalins. When acted upon by alcoholic solution of potash, they are split up into hydrochloric or hydrobromic acids, and the chlor- and brom-naphthalins already mentioned. The following is a list of these chlorides and bromides of naphthalin, or of its derivatives:—

Chloride of naphthalin	$C_{20}H_8, Cl_2$
„ brom-naphthalin	$C_{20}H_7Br, Cl_2$
Bromide of tribrom-naphthalin	$C_{20}H_5Br_3, Br_2$
Bichloride of naphthalin	$C_{20}H_8, 2Cl_2$
Bichlorobromide of naphthalin	$C_{20}H_8, Cl_3Br$
Bichloride of chlor-naphthalin	$C_{20}H_7Cl, 2Cl_2$
„ bichlor-naphthalin	$C_{20}H_6Cl_2, 2Cl_2$
„ bibrom-naphthalin	$C_{20}H_6Br_2, 2Cl_2$
Bibromide of bichlor-naphthalin	$C_{20}H_6Cl_2, 2Br_2$
„ bromochlor-naphthalin	$C_{20}H_6BrCl, 2Br_2$
„ bibrom-naphthalin	$C_{20}H_6Br_2, 2Br_2$
Bichloride of bibrom-chlor-naphthalin	$C_{20}H_5Br_2Cl, 2Cl_2$
Bibromide of tribrom-naphthalin	$C_{20}H_5Br_3, 2Br_2$

Paranaphthalin, or *anthracin* ($C_{30}H_{12}$)? This polymeride of naphthalin accompanies the latter body towards the end of the process of distilling coal-tar. It is insoluble in alcohol; any naphthalin is therefore easily dissolved out by that liquid. It is a white solid; melting point 356° Fahr. At a temperature above 572° , it boils, sublimes, and condenses in lamellar crystals. Turpentine readily dissolves it. Chlorine converts it into *chloranthracin*, a crystalline body containing $C_{30}H_{10}Cl_2$. A corresponding nitric derivative, $C_{30}H_{10}(NO_2)_2$, also exists.

Metanaphthalin, or *retisterin*, is another polymeride of naphthalin, obtained during the distillation of rosin. Its melting-point is 153° Fahr., boiling point 617° . It is crystalline, slightly soluble in cold alcohol, but readily so when heated; it is also soluble in ether, naphtha, and turpentine.

Naphthylamine ($C_{20}H_9N = NH_2(C_{20}H_7)$). *Naphthalidam*. *Naphtha-*

lidine. Obtained by the reduction of nitronaphthalin, either with acetic acid and metallic iron, or with sulphide of ammonium.

Naphthylamine forms white, silky needles. It melts at 122° Fahr., and at 572° sublimes without alteration. It has a disagreeable odour and bitter taste, is almost insoluble in water, but very soluble in alcohol or ether. It combines with acids to form white crystalline salts. The *hydrochlorate* contains $C_{20}H_9N, HCl$; the *nitrate* $C_{20}H_9N, NHO_3$; the *neutral oxalate* $2C_{20}H_9N, C_2O_6, 2HO$; and the *acid oxalate* $C_{20}H_9N, C_2O_6, 2HO$. Dr. Schiff has also recently ('Ann. Chem. Pharm.' ci. 90), obtained the following derivatives of naphthylamine. *Iodide of ethyl-naphthylammonium* ($N(C_2H_5), (C_{20}H_7)H_2, I$); shining four-sided prisms. *Bromide of ethyl-naphthylammonium* ($N(C_2H_5), (C_{20}H_7)H_2, Br$); acicular crystals. *Naphthyl-urea* ($C_2H_5(C_{20}H_7)N_2O_2$); shining, flat needles. *Bromide of naphthylammonium* ($NH_2(C_{20}H_7), Br$). *Oxynaphthylamine* ($NH_2(C_{20}H_7), O_2$), produced by the characteristic reaction of naphthylamine with perchloride of iron, chlorides of gold, platinum, mercury, zinc, chromic acid, or nitrate of silver. It is the substance called *naphthomein* by Piria. *Dinaphthyl-sulphocarbamide* ($NH_2(C_{20}H_7)_2, C_2S_2$) obtained on heating naphthylamine with bisulphide of carbon in a sealed tube for some hours. By heating naphthylsulphocarbamide with anhydrous phosphoric acid, Mr. Hall has produced *sulphocyanide of naphthyl* ($C_{20}H_7, C_2NS_2$). *Naphthylcarbamide*, obtained by the action of potash on naphthylsulphocarbamide, is also powerfully attacked by anhydrous phosphoric acid and yields, among other bodies, *Cyanate of naphthyl* ($C_{20}H_7, C_2NO_2$). Hyponitrous acid acts upon naphthylamin, and gives rise to *Nitroso-naphthylin*, a purple substance containing, according to Church and Perkin, ($C_{20}H_9(NO_2)N$): it somewhat resembles Laurent's *carminaphte* obtained by the action of chromic acid upon naphthalin.

Nitronaphthylamine ($C_{20}H_8(NO_2)N$) is a nitric derivative of naphthylamine obtained on treating binitronaphthalin with sulphuretted hydrogen, the ultimate product, however, is

Azonaphthylamine, or *seminaphthalidam* ($C_{20}H_{10}N_2$). The following equation explains its formation:—

It is deposited from alcohol in long, brilliant needles. Its salts are crystalline, and have mostly an acid constitution.

Thionaphthamic acid ($C_{20}H_9NS_2O_6$) and *naphthionic* (or *sulphonaphthalidamic acid*) ($C_{20}H_9NS_2O_6$) are isomeric sulphuric derivatives of naphthylamine. They form crystallisable salts with bases.

Oxynaphthalic acid ($C_{20}H_6O_6$). This substance has not yet been produced (unless alizarin be identical with it), but two derivatives of it, containing respectively one and five equivalents of chlorine in the place of one and five of the hydrogen in the above formulæ, are well known.

By the action of nitric acid upon bichloride of chlornaphthalin we obtain *chloride of chloroxynaphthyl* ($C_{20}H_4Cl_2O_4$) called also *oxychloronaphthalose* and *oxide of chloroxenapftose*. Alcoholic solution of potash converts it into chloroxynaphthalate of potash, and from this salt *chloroxynaphthalic acid* ($C_{20}H_5ClO_6$) is easily isolated. *Chloride of perchloroxynaphthyl* ($C_{20}Cl_6O_4$) obtained by the action of nitric acid upon sexchlornaphthalin is converted by alcoholic potash into perchloroxynaphthalate of potash, and from this salt the *perchloroxynaphthalic acid* or *chl-roxynaphthalesic acid* ($C_{20}HCl_5O_6$) is easily isolated.

NAPHTHYL-THIOSINNAMINE. [MUSTARD, OIL OF.]

NAPHTHYLUREA. [NAPHTHALIC GROUP.]

NAPIER'S BONES, or RODS, a contrivance of Napier to facilitate the performance of multiplication and division, explained by him in his 'Rabdologiæ, seu numerationis per virgulas libri duo,' Edinburgh, 1617, 12mo. The invention would have been perhaps more employed,

but for his discovery of logarithms; and even yet it might be used with advantage by young arithmeticians in verification of their work. We shall therefore describe it, with a very slight modification, which somewhat facilitates its use.

The preceding cut represents one of the rods belonging to the number 3. It is a parallelogram with an angle of 45°, containing nine equilateral parallelograms, with one vertical diagonal in each. In these are distributed, in a manner which will be visible at a glance, the multiples of the number which stands at the head, up to nine times. A sufficient number of rods must be provided for each of the headings 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, so that by placing the proper rods side by side, any number may be seen at the head, as in the following diagram, which represents rods in juxtaposition ready for the multiplication of 709958.

709958
32978
5679664
4969706
6389622
1419916
2129874
23412994924

If we wish to multiply by 32978, we look at the eighth column of multiples, in which we see the following disposition of figures (which, however, it is not necessary to write down afresh):—

602204
507746

These may be added on the rods, and the result 5679664 written down in its proper place. The same is done with the other digits, and the results are added in the usual manner.

The only difference between the preceding description and Napier's rods is, that in the latter the rods are upright, and the additions that are made from the rods are therefore made diagonally. The compartments should be made large enough to allow of the figures which are to be added standing directly under one another. They represent a method on paper of the Hindoo arithmeticians, of which Napier knew nothing.

Napier's bones, as they were called, have been much more often described in historical works than in those intended for use. Sir Walter Scott must have had an indistinct remembrance of them, without however knowing what the phrase meant, when he made Davie Ramsay, in the 'Fortunes of Nigel,' swear by "the bones of the immortal Napier."

NAPLES YELLOW. A pigment used by artists. It consists of antimoniate of lead, and is produced by heating antimoniac acid with oxide of lead.

NARCEINE. [OPIUM, ALKALOIDS OF.]

NARCETINE. [OPIUM, ALKALOIDS OF.]

NARCITIN. A non-azotised emetic substance found in the white narcissus.

NARCOGENINE. [OPIUM, ALKALOIDS OF.]

NARCOTICS (from the Greek adjective *ναρκωτικός*, which is from *ναρκή*, a stiffening, stupor, or insensibility), a class of medicines which may be defined—agents which, in moderate doses, cause a temporary increase of the action of the nervous and also of the vascular system, followed more or less speedily by a marked diminution of this action, terminating generally in sleep. When the dose is large, the excitement is scarcely perceptible; while the diminished power of the nervous system is so manifest, that an appearance of coma or apoplexy is induced. All the agents included in this class are capable of producing a state termed narcosis, or narcotism, which, if not quickly removed by a natural subsiding of their influence, or by artificial means, may terminate in death. Many of them are therefore as familiarly known as poisons as therapeutic agents. It is the consideration of them however in this latter quality which is to be entered on in this place. Their power of inducing sleep has procured for them the name of hypnotics, or soporifics; and the property which many of them possess of alleviating pain, by blunting the sensibility, has obtained for them the appellation of anodynes [ANODYNES], or, from one of the best known among them, simply opiates.

The most important consideration respecting them is the circumstance of their depressing action being always preceded by a stimulant. This peculiarity renders their employment difficult in some cases and improper in others. "Narcotics must be distinguished from stimulants on the one hand, and from sedatives on the other; and the distinction is the more necessary, because in nature the narcotic principle is generally combined with one or other of these: hence the contradictory and unsatisfactory reports of the value of different narcotic remedies, and the difficulty experienced in their application by those who do not know the reason why opium suits one case, hyoscyamus another." (Billing's 'First Principles of Medicine,' 3rd edit.) The progress of chemistry, by isolating the various active principles existing in the same natural compound, has lessened the difficulty attendant on their administration; still, as no one can be said to act in a manner precisely similar to another, a correct knowledge of each is desirable in order to ensure the selection of that which is best suited to the case. Diversified as they are in their nature and modes of action, there is this common property, that they all make a direct impression on the extremities of the nerves (to whatever part of the body, with few exceptions, they are applied); but their full and ultimate effects do not take place till they are absorbed, and mingled with the circulating fluid.

A slight glance at their action on the different systems of the body will furnish a useful guide in their administration. A full dose of a narcotic introduced into the stomach will, if that organ be empty, destroy the desire for food, while, if it contain food, the digestive process is suspended or rendered slower. Their frequent or continued use is therefore very injurious to that function, on which all the others depend, namely, nutrition; as is displayed in the persons of opium-eaters of the East. Further, should any considerable irritation or subacute inflammatory condition of the mucous coat of the stomach exist, they cause an aggravation of the febrile symptoms, and either in common or cancerous ulceration of that organ they cause great uneasiness. Though their primary effect on the vascular system be stimulating, and many of them send thereby a large quantity of blood to the brain (probably the source of their soporific property), their secondary effect is depressing; and in this the respiratory organs participate. This is at once a source of utility and of danger, for by moderating the action of the heart and lungs, the respiration is rendered slower, an advantage in most inflammatory complaints; but when pushed too far, the blood is not sufficiently aerated, and partaking too much of the nature of venous blood, it does not prove a sufficient stimulus to the brain and other organs.

Their action upon the secreting system is not very uniform, nor are all writers agreed as to its nature. Opium generally checks most of the secretions, except that of the skin, and causes heat, thirst and constipation. Hyoscyamus rarely causes any of these states, but on the contrary is rather laxative, and aconite greatly increases the secretion of the bile and also of the skin. Many natural compounds have an acrid principle combined with the narcotic, and hence are termed *narcotico-acrids*, such as aconite, squil, colchicum, hellebore, &c.: these generally augment the mucous and other secretions, though they produce narcotism in excessive doses.

Lastly, some of them possess greater influence over one set of nerves than the other, and expend their energy on the nerves of motion, or of sensation, according to their nature.

No set of medicines have their action more modified by a variety of circumstances—such as the quantity given, or the frequency of repetition, also the force of habit, climate, or season, but above all by idiosyncrasy. Age also has an important share in determining the amount of action. Children do not in general bear them well, and therefore though they are very subject to convulsive and spasmodic diseases, other means should be employed, especially the removal of the source of irritation, when practicable. The various nostrums recommended for children generally contain some narcotic, and prove a fertile cause of the mortality of early life. [ANTISPASMODICS.] The administration of narcotics requires more knowledge and judgment than that of any other class of remedies, and should only be had recourse to under competent advice.

In case of over-dose or accidental poisoning, the following observations may be useful. The stomach being rendered insensible to the irritation of emetics, these are generally useless, and much valuable time is lost by administering them. Where better means cannot be had, sulphate of zinc (white vitriol) dissolved in water, or a table-spoonful of flour of mustard diffused through a pint of warm water, may be given, accompanied with pressure on the pit of the stomach, and at the same time tickling the throat with a feather. Neither ipecacuan nor tartar emetic should be used; the latter is particularly unfit. [BELLADONNA.] The stomach-pump is the surest means of emptying the stomach, and should be used as soon as possible. If the brain appear much oppressed, the countenance flushed, and the pulse full, moderate blood-letting will be serviceable, especially if artificial respiration be subsequently employed. When the water brought up by the stomach-pump is clear and devoid of any smell of the poison, which will prove that all the hurtful material has been evacuated, then, and not till then, vinegar may be given to the patient, who should also be kept moving about, and not suffered, if possible, to sink into a state of slumber. Coffee is a very useful beverage, and still more a drink made by boiling twelve ounces of vinegar, and pouring it immediately on three ounces of roasted and ground coffee, or by boiling the coffee in the vinegar, straining it, then adding half an ounce of sugar, and giving it in small quantities to the patient every quarter or half hour. This can be prepared while the stomach-pump is being used, and is one of the most efficacious means of counteracting the narcotic principle. Vinegar given while any of the poisonous substance is in the stomach only increases its deleterious property. [ANTIDOTES.] See Pereira's 'Materia Medica,' for the mode of action of the different narcotic substances, i., p. 200; and Christison 'On Poisons.' The vapours of several fluids, such as sulphuric æther, chloroform, amyl, &c., have been used to produce insensibility, particularly during surgical operations. These have been already treated of under ANÆSTHETICS.

NARCOTINE. [OPIUM, ALKALOIDS OF.]

NASAMONNES (*Nasamōnes*), a barbarous and nomadic people in Libya, who dwelt on the coasts of the Greater Syrtis. According to Strabo they were bounded on the west by the Psylli, and extended westward as far as the Philæian Altars, which were at the southern extremity of the Greater Syrtis (xvii., p. 836, 838, Casaub.). Herodotus places them farther to the west, and states that they occupied the country of the Psylli (iv. 173). On the east they extended beyond the Syrtis, and were bounded by the Auschise, a small tribe, who dwelt to the west of the Cyrenaica (Herod., ii. 32; iv. 172). Inland they had dominion as far as the oasis of Augila, in the great desert of Barca, which is 180 miles south-east of Barca, and is at the present day one of the resting-places of the caravans which trade between Cairo and Fezzan. [AUGILA, in GEOG. DIV.] The Nasamones were accustomed to leave their cattle on the coast in the summer season, and go to Augila to gather dates (Herod., iv. 172). Pliny (v. 5) also places the Nasamones on the Syrtis, and says that they were anciently called Mesamones by the Greeks, because they were situated between two quicksands (*μέσος ἄμμος*); meaning perhaps the two Syrtis, which however is not the case. All these may have been true at various times, for they were a numerous and wandering race, pressed on one side by the Greeks of Cyrene, and on another by the Carthaginians. Their territory, at the time of its greatest extent, must have extended for 400 miles from east to west along the Mediterranean, inland as far as Psylli and Augila.

The Nasamones are described by Herodotus (iv. 172, 190) as a numerous nomadic people, who were cattle breeders, who had a community of wives, were accustomed to swear by the tombs of the bravest and justest of their ancestors, and pledged their faith by drinking out of the hands of one another, or by licking dust out of one another's hands, if they had no water; they are described by Lucan ('Phars.', ix. 404) and Q. Curtius (iv. 7) as a barbarous tribe, who lived by the plunder of the vessels shipwrecked on their coast. Bruce, who was shipwrecked on this coast, found that the present inhabitants followed the same practice. (Rennell's 'Geography of Herodotus.')

The Nasamones were driven into the interior of the country by the Romans in the time of Domitian. (Dionys. 'Perieg.' ed Hudson, iv. 208; Eusebii, 'Chron.' Ol. cexvi.; Joseph., 'Bell. Jud.' ii. 16, § 4.) Ptolemy places them as far inland as Augila.

Herodotus gives (ii. 32) an interesting account of an exploring expedition, undertaken by five young men of this country, who crossed the great Libyan desert, and, after traversing extensive marshes, came to a large river flowing from west to east, with crocodiles in it, which he considered to be the Nile, but which many commentators have supposed to be the Niger. [NIGER.]

NASCENT STATE. When an elementary or compound substance is liberated from some chemical combination in which it had previously existed; the element or substance so liberated is, at the moment when it is set free, said to be in the *nascent state*. In this condition it is, as a general rule, capable of exerting far more energetic affinities than it exhibits when brought into contact with other bodies after it has been set at liberty. Thus acetic acid may remain in a vessel filled with oxygen for centuries without undergoing any change, but if the acid be brought into contact with oxygen at the moment when the latter is liberated at the positive pole of a voltaic decomposition cell, it is

instantly oxidised and converted into carbonic acid and methyl. In like manner free chlorine gas has no action upon gold, but it instantly attacks the metal when in the nascent state, that is when it is liberated, in contact with gold, from any of its compounds. Such an exaltation of chemical affinity at the moment of separation is not peculiar to gases, it is also noticed in the case of liquids and even solids. The cause of this phenomenon is involved in considerable obscurity; we are however indebted to Professor Brodie for the only philosophical explanation of it which has been attempted, and to this the reader is referred ('Philosophical Transactions for 1850,' p. 759).

NASIREANS. [NAZARENES.]

NATIONAL ASSEMBLY, the name by which the States General (États Généraux) of France had been sometimes known, and which was fully adopted under Louis XVI., when the three estates were united. Among the earliest acts of the National Assembly were the publication of the 'Declaration of the Rights of the Man and the Citizen,' a piece of absurd and incongruous declamation; and the preparation of a new constitution. In September, 1791, this was presented to the king for his sanction, which was accorded, and the assembly dissolved itself on the 30th of the same month. The first National Assembly is frequently termed 'l'Assemblée constituante,' from its having framed the constitution. The constitution lasted about twelve months, and was succeeded by the Republic.

NATIONAL DEBT. The National Debt consists of money borrowed from individuals, under the authority of the legislature or the government, and the security for which is all the property of the country. The money so raised is not to be paid on demand, but only the interest thereon, but, from its being transferable, this occasions no inconvenience to the individual, because he can raise money by the sale of the amount of his holding, according to the estimated value of his security, and the value of money at the time he feels a necessity for it.

The national debt, we may observe, consists principally in most countries, as well as our own, of money raised as above stated, and this is called the Funded Debt; but in Great Britain there is also an Unfunded Debt, which consists of money raised by granting annuities for life or term of years, and by Exchequer Bills, which are renewed from time to time. [EXCHEQUER BILLS.]

The richer a country becomes the greater is the security, and a loan is consequently acquired on easier terms. By this process of borrowing, a country whose credit is unimpeached is, when in immediate want of money, enabled to raise the sum required without overloading the springs of its natural industry. A man who has more money than he can advantageously employ in manufactures or commerce, or persons who have no facilities or faculties for so employing it, will be glad to accept 4 or 5 per cent. for funds that cannot be employed more profitably; while those who are able to make 10 per cent. by the addition of their own exertions, will not invest their funds in a government loan. The raising of money by loan, thus furnishes a means of securely employing sums that might possibly otherwise remain unproductive, produce a glut of money, or be employed in unprofitable speculation. It is a power, however, that requires to be prudently used; for if loans are too frequently called for they must have the same effect as exorbitant taxes in crippling the general fund for the employment of industry, besides imposing a heavy load on posterity in the shape of interest. But we shall enter no farther on the interminable questions of the advantages and disadvantages of a National Debt, as it has been adopted by almost every civilised country, but proceed to describe its use and progress amongst ourselves.

The contracting of the National Debt cannot be said to have begun before 1691. The kings of England had indeed been accustomed from a remote date to borrow money upon emergencies, but on such occasions the revenues of the crown were pawned for the amount, which was seldom beyond what could by that means be repaid in a few years. The earliest instance of this borrowing which we have on record was in the reign of Richard I., when money was wanted to defray the expense of his crusade to the Holy Land. Loans were made upon Exchequer tallies by the Jews; and the Jews got what they could in the shape of usury. Loans were also raised upon debenture and privy seal; and sometimes the capitalist would not lend unless he had the security of the king's jewels. There was a perpetual struggle between borrower and lender—between force and fraud. In three or four centuries loans to the crown ceased to be so much a personal affair, and the Parliament stepped in to give additional security and confidence to lenders. But every such loan was of temporary duration, even when public securities bearing interest became negotiable in 1664. In 1672, when 1,328,000*l.* of revenue was pledged for the immediate payment of loans to the goldsmiths or bankers, whose advances were chiefly made by funds intrusted to their keeping, Charles II., being somewhat straitened by an expensive Dutch war and a few witty mistresses, shut up the Exchequer, issuing a proclamation announcing that the 1,328,000*l.* should be paid in a year. There was universal panic and much private ruin. The principal was never redeemed; but the king charged his hereditary revenue with payment of interest upon this sum, which interest was duly paid to 1684. Law-suits were instituted by the creditors against the crown when this interest was stopped. At length an Act of Parliament was passed in 1699, by which, after the year 1705, the creditors were to receive interest

of 3 per cent. upon the original amount, to be redeemed whenever the government should pay a moiety thereof. That moiety of 660,263*l.* is a part of the present funded debt. But even for some few years after the accession of William and Mary the borrowings of the government were for short periods only. In January, 1693, an act was passed which empowered the raising a loan of a million by way of life annuities, at 10 per cent. till 1700, and afterwards, and during the life of the last survivors of the public creditors, at 7 per cent. The first loan of a permanent character arose out of the chartering of the Bank of England in 1694, when its capital of 1,200,000*l.* was lent to the public at 8 per cent. interest. A power of repayment was reserved on this occasion by the crown, but no corresponding right of demanding payment existed on the part of the bank. Still the system of terminable annuities was that adopted by the statesmen of that day as long as practicable.

This cautious proceeding could not be long continued. The expensiveness of the wars in which the nation was engaged at the end of the 17th century made it necessary to incur debts beyond the means of their prompt redemption, and at the peace of Ryswick, in 1697, the debt amounted to 21½ millions. During the next ten years, although the country was again involved in a continental war, its amount was reduced to little more than 16 millions, and the greatest efforts were made to raise money without imposing any lasting burden on the people. These efforts indeed soon found their limit, and at the accession of George I. in 1714, the debt had accumulated to the amount of 54 millions, an amount which excited great uneasiness and caused the House of Commons to declare itself under the necessity of making efforts for its reduction. In 1717 the debt amounted to 48½ millions, and the annual charge in respect of the same to 3,117,296*l.* A great part of this debt consisted of annuities granted for 99 years, the money obtained for which had varied from 15 to 16 years' purchase.

In the year 1720 the South-Sea Act was passed, authorising the company to take in, by subscription or purchase, the redeemable debts of the nation, the object being to reduce all the debts under one head of account at one uniform rate of interest. In the accomplishment of this scheme the projectors only partially succeeded, while the disgraceful frauds by which the proceedings of the company at that time were marked, led to a parliamentary investigation which caused the disgrace of some of the ministers, the chancellor of the exchequer being expelled the House, and committed to the Tower for his share in the plot. It is not the least remarkable circumstance attending this scheme that it was attempted at the same time with the equally famous Mississippi scheme, which, with a similar object, was projected in France by John Law, under the sanction of the Regent Duke of Orleans. [LAW, JOHN, in BIOG. DIV.]

In 1736 the public debt in England amounted to about 50 millions, but the annual charge had been reduced below two millions. At the peace of Aix-la-Chapelle, in 1748, the national debt exceeded 78 millions, but in the following year the public obtained some relief from the burden through the lowering of the rate of interest. Little else was done in the way of alleviation at this time, and at the breaking out of the Seven Years' War, in 1756, the debt still amounted to 75 millions. A public writer of some repute, Mr. S. Hannay, says, at that date, "It has been a generally received notion among political arithmeticians, that we may increase our debt to 100,000,000*l.*, but they acknowledge that it must then cease by the debtor becoming bankrupt." Those who in more recent times have witnessed the addition year after year to the debt of sums equal to more than the difference between its then amount and its declared limit, may smile at this prediction, and learn to put little faith in opinions which are not based upon previous experience.

When the Seven Years' War was ended by the peace of Paris, the debt reached 139 millions, and the annual charge was 4,600,000*l.* During the twelve following years, a period of profound peace, only 10,400,000*l.* of the debt was discharged. The war of the American Independence raised the debt from 129 to 268 millions, and the annual charge in respect of the same to 9,512,232*l.* So little was done in the way of liquidation during the following ten years, that at the beginning of the war of the French Revolution the debt still amounted to 260,000,000*l.*, and its annual charge to 9,437,862*l.* The outlay occasioned by the prosecution of that war was great beyond all precedent. Between 1793 and the peace of Amiens the addition made to the capital of the debt amounted to 360 millions, and the annual burden was increased from 9,437,862*l.* to 19,945,624*l.* Between the recommencement of the war in 1803 and its termination after the battle of Waterloo in 1815, there were added 420 millions to the capital of the debt, which then amounted, including the unfunded debt, to 885 millions, and the annual charge upon the public exceeded 32 millions of money. This enormous, this frightful rate of progression, appears to have excited far less alarm than was expressed at the comparatively trifling additions made at the beginning of the funding system, a consequence which probably must be in great part attributed to the establishment of the sinking fund, and to the hope which it held out of cancelling at no very distant period each amount of debt successively increased.

A plan for the gradual extinction of the National Debt by the establishment of a sinking fund was proposed and partially applied in 1716 by Sir R. Walpole. The scheme for that purpose proposed under

the same name by Mr. Pitt in 1786 had a greater show of reality about it. By this scheme the sum of one million was annually set apart from the income of the country towards the extinction of its debt. Other sums were rendered accessory to the plan, and it was supposed that at the expiration of 28 years the annual income of the sinking fund would amount to four millions, a part of which might then be applied towards relieving the burden of the public. So far the project bore the stamp of reasonableness and prudence: had the fund of one million annually assigned to commissioners been an actual surplus of income over expenditure, its operation must speedily have been highly advantageous to the country. The fallacy consisted in this, that the sums devoted to it were borrowed for the purpose. The only real advantage secured by this means arose from the unfounded confidence which it imparted to the public, under which they willingly bore a higher rate of taxation than might have been tolerable but for the expectation of future relief through its means. Now that the absurdity is acknowledged of borrowing in order to pay off debt, which absurdity would in the case of an individual always have been apparent, it is difficult to account for the blindness with which the whole nation clung to this so-called fund as the certain means of extinguishing the debt which in effect it contributed to augment through the less advantageous terms upon which the money was borrowed than those upon which an equivalent amount of debt was afterwards redeemed. The difference between the average rates at which money was borrowed and at which purchases were made by the Commissioners who managed the sinking fund between 1793 and 1814 was such, that through the operations of the fund, upon which such confident hope of relief was placed, the country owed upwards of 11 millions more at the end of the war than it would have owed but for those operations. At the period just mentioned the annual income of the sinking fund amounted to 13,400,000*l.*, arising from dividends on stock purchased by the commissioners with funds borrowed at a higher rate of interest for the purpose. It was impossible however during a time of peace to raise by means of taxes so large an amount, in addition to the actual current expenditure of the country and the interest upon the unredeemed portion of the debt. During the war, when the deficiency of income was covered by yearly loans, the fallacy was not quite so apparent as it now soon became, for a few years after the peace the deficiency in the public income was borrowed from the sinking fund commissioners by parliament, a course which served to render the absurdity only the more apparent, and in 1824 the plan of keeping up a large nominal sinking fund in the absence of actual surplus income was abandoned.

The amount of the National Debt unredeemed on the 5th of January, 1816, was stated to be as follows in the fourth Report of the select committee of the House of Commons on public income and expenditure:—

3 per cent. stock	£580,916,019
3½ "	10,740,013
4 "	75,725,504
5 "	148,930,403
Perpetual annuities	816,311,939
Terminable annuities, 1,894,612 <i>l.</i> , equal to an estimated capital of	30,080,347
Unfunded debt	38,794,038
Total of unredeemed debt	£885,186,324

The annual charge upon which was—

Interest upon perpetual annuities	£28,278,919
Terminable annuities	1,894,612
Interest on unfunded debt	1,998,937
Charge for management paid Bank of England	284,673
Total annual charge	£32,457,141

The experience of the last fifty years has proved that the only important relief from the pressure of debt to be obtained, even during a profound and long-continued peace, will probably be derived from the lowering of the rate of interest. The price of 5 per cent. stock at the beginning of 1822 was advanced to 6 or 8 per cent. above par, and advantage was taken of this circumstance to induce the holders to exchange each 100*l.* of 5 per cent. annuities for 105*l.* of 4 per cent. annuities. On this occasion 140,250,828*l.* of 5 per cent. stock was cancelled, and 147,263,328*l.* of 4 per cent. stock was created, the annual charge being by this means reduced by the sum of 1,122,000*l.* In 1824 a further saving of 381,034*l.* per annum was effected by reducing to 3½ per cent. the interest payable on 76,206,822*l.* of 4 per cent. stock; and in 1830 a further abatement of one-half per cent. was effected on the 4 per cent. stock created in 1822, whereby the sum of 700,000*l.* per annum was saved to the public.

Some progress was made after 1816 in the reduction of debt by the employment for that purpose of actual surplus revenue. An addition on the other hand was made to the public burdens by means of the grant of 20,000,000*l.* voted by parliament for compensation to the owners of slaves in the British colonies who were emancipated by the act of 1833. Down to the commencement of the war in the Crimea in 1854, a reduction greater or less had taken place every year, but that

war occasioned an expenditure that created a loan for 20,000,000*l.*; and the suppression of the rebellion in India, though the loan occasioned by that war was charged on the Indian revenue, has prevented any further diminution. The unredeemed funded and unfunded debt which existed on March 31, 1857, and the annual charge thereon, were as follows:—

	Rate of Interest.	Amount. £	Annual Interest. £
New annuities	2½	2,993,331	74,833
Consolidated annuities	3	395,068,382	11,852,051
Reduced annuities	3	113,817,476	3,293,524
New annuities	3	213,143,113	6,394,293
Debt to Bank of England	3	11,015,100	330,453
New annuities	3½	240,746	8,426
"	5	431,124	21,556
Total permanent debt		£736,009,272	£22,075,136

The unfunded terminable annuities were—

For life	9,984,253	1,030,856
For terms of years	2,710,125	867,490
Long annuities (expired 1860)	3,008,922	1,156,744
Annuities (expire 1867)	4,906,417	585,740
" (expire 1885)	2,059,810	116,000
Tontine and Exchequer { English	161,748	15,639
life annuities. { Irish	195,766	26,784
Exchequer bonds	418,300	11,503
Total terminable debt	£23,445,341	£3,810,056

The Irish permanent debt was 43,692,145*l.*; the terminable debt 517,200*l.*, and the total amount of interest payable was 1,526,793*l.* The total funded debt of the United Kingdom was 779,701,417*l.*, the unfunded debt, 24,032,541*l.* In 1859 the funded debt had increased to 805,078,554*l.*, and the interest to 28,204,299*l.*

The diminution of the annual burden in the course of twenty-three years, from 1816 to 1839, was 3,150,710*l.*, at which rate the total extinction of the debt would not have been effected until the year 2053. The slow progress made in this direction stands in striking contrast to the rapidity with which the load was accumulated, the entire diminution effected during twenty-three years of peace being scarcely equal to the additions made during some of the individual years of the war.

In comparison with the debt entailed upon the British nation by all previous wars, the war of the French revolution, costing, in addition to a vast amount of current taxation, a permanent debt of six hundred millions, may be regarded, in its pecuniary sacrifices, the most fatal contest in which a great nation was ever engaged; but if considered as a struggle for national existence, the cost may be thought not disproportionate to the object gained. Of the necessity for that war, there are very opposite views, into a discussion of which it is not our business here to enter.

From 1816 to 1854, thirty-eight years of peace had reduced the capital of the debt seventy-seven millions. Two years of war lifted it up thirty-eight millions; again to be slightly reduced when the short but expensive contest with Russia was at an end. The vast increase of capital and population since the beginning of the century makes the interest of the debt, enormous as it is, fall lighter upon individuals. Roughly estimated, the debt of 1801, whose interest amounted to twenty millions, was a burden of 2*l.* per head upon each of the population of Great Britain. In 1860, the debt, whose interest amounts to twenty-eight millions, is a burden upon each of the British population of 1*l.* 4*s.* per head.

We have constructed a table, out of the official abstract, which will demonstrate, beyond the possibility of cavil, that the vast national debt of this country has been created by its wars. It is not for us to argue for or against the necessity for those wars. It may be certain that they could not have been carried on by laying the load of taxation upon the existing tax-payers, at their commencement, or during their continuance; but it is equally certain that the power of burdening posterity may be a very dangerous power, liable to plunge a nation into unjust and unnecessary quarrels; and, carried to excess, imposing a perpetual load upon every exercise of productive industry. The demands upon that industry to repair the natural consumption required for the ordinary wants of man is unceasing. Production, however large, can with difficulty keep pace with the extraordinary waste of war. The war expenditure from 1793 to 1815 was upon so enormous a scale, that the total amount paid and expended in one year had risen from 19,859,123*l.* in 1792, to 92,280,180*l.* in 1815, with about 35 millions extra in the two years of 1813 and 1814. Without the facility of borrowing, this vast amount could not have been raised. Whatever may be our political views, we may therefore unite in the conclusion that a national debt may be a good servant in times of extreme need, but a bad master if its aid be habitually invoked.

Period.	Debt.	Interest.	Years of War.	Increase of Debt in Years of War.	Remarks.
	£	£		£	
1691	3,130,000	332,000			
1701	12,552,486	1,219,147	1691—1697	11,392,925	French War.
1714	36,175,460	3,063,125	1702—1713	21,932,622	War of the Succession.
1748	75,812,132	3,165,765	{ 1718—1721	14,025,424 }	Continental Wars.
			{ 1740—1748	22,531,551 }	
1763	132,716,049	5,032,733	1756—1763	58,141,024	Pitt's Administration.
1792	239,663,421	9,432,179	1774—1783	104,681,213	American War.
1815	861,039,049	32,645,618	1793—1815	621,375,628	War of French Revolution and against Napoleon.
1859	805,078,554	28,204,299	1854—1856	32,793,303	War with Russia.
Amount of National Debt 1859				£886,873,690	From 1691 to 1859.
				805,078,554	
Decrease in Years of Peace				£81,795,136	
					Years of War 82
					Years of Peace 86

It will be seen, on comparing the above statements for 1815 and 1857, that the terminable annuities have increased from 1,894,612*l.* to 3,810,623*l.*, equal to an estimated capital of 23,445,341*l.* A part of the terminable annuities expired in 1860, and after that time other portions will fall in; so that without looking to any redemption of debt from surplus income, or to any further reductions in the rate of interest, the next twenty-eight years will be productive of still further relief.

The functions intrusted to the Bank of England with reference to the National Debt do not extend to the transaction of any matter connected with its reduction. Such business is placed under the control of a body of commissioners, who act *ex officio* under the provisions of an act of parliament. This board is composed of the speaker of the House of Commons, the Chancellor of the Exchequer, the accountant-general of the Court of Chancery, and the governor and deputy-governor of the Bank of England. The greater part of these commissioners do not take any part in the management of the business, the details of which are attended to by permanent officers, namely, a secretary and comptroller-general, and an actuary, with an adequate establishment of assistants and clerks: the ultimate control is exercised by the chancellor of the exchequer for the time being, assisted by the governor and deputy-governor of the Bank of England.

NATIONAL GALLERY. The credit of founding a National Gallery of paintings is due to the government of Lord Liverpool. Often as the importance of such a gallery had been urged, it was not till 1823 that the intention was seriously entertained by the govern-

ment. The subject was in that year first formally brought before parliament by the Hon. George Agar Ellis, afterwards Lord Dover, but the merit of the suggestion is ascribed to the king, George IV. It was announced that Sir George Beaumont, one of the most influential art-patrons of the day, was willing to present the more valuable portion of his own collection to the nation as soon as it should be decided to commence the formation of a national gallery; that a favourable opportunity offered for the purchasing another choice collection; and that the two would together form an excellent nucleus for a great public gallery. Parliament approving, Mr. Angerstein's collection was purchased for 57,000*l.*, and the purchase, with the addition of 3,000*l.* for the expenses of the establishment, was sanctioned by the usual vote in April 1824.

By a Treasury Minute of the following July, a committee of six trustees was appointed the superintending body over the gallery; the active management being intrusted to a keeper, under whom was an assistant keeper and secretary; and this, with slight modification, continued to be the arrangement until the reconstitution of the gallery in 1855.

The Angerstein collection was opened to public inspection at Mr. Angerstein's house in Pall Mall on the 10th of May, 1824. Sir George Beaumont's pictures were not added till somewhat more than a year later. The Angerstein collection consisted of 38 pictures, of which 29 were by the old masters, and 9 by British painters. The purchase was in every respect an admirable one. Most of the pictures were of a high class, unquestionably authentic, and of a kind to secure the public

interest and admiration. At the head of them was the masterpiece of Sebastian del Piombo, one of the pictures placed by common consent among the very finest works of the best age of painting; and one in which is recognised a combination of the art of the painter whose name it bears, and of the greater hand of Michelangelo. By Sebastian's rival, Raffaele, there was the noble portrait of Julius II. Of Titian, Correggio, and the Carracci, there were also examples, though of inferior value. The painters of the Low Countries were well represented by the 'Rape of the Sabine Women,' by Rubens; by Rembrandt's 'Woman taken in Adultery,' and 'Adoration of the Shepherds;' and by Vandyck's 'St. Ambrose and the Emperor Theodosius;' while of the Italo-French school there were a very characteristic 'Bacchanalian Scene,' by Nicolas Poussin; a couple of landscapes by Gaspar Poussin; and no less than four landscapes by the prince of landscape-painters, Claude Lorraine, two of them being of large size and great excellence. The nine English pictures consisted of Hogarth's inimitable portrait of himself, and his admirable series entitled 'Marriage à la Mode;' Reynolds's masculine portrait of Lord Heathfield, the Defender of Gibraltar; and Wilkie's brilliant 'Village Festival.' The gift of Sir George Beaumont was a worthy pendant to the Angerstein purchase. It consisted of sixteen pictures, of cabinet size, but for the most part of excellent quality. Himself a zealous (amateur) landscape painter, it was, as might be expected, in landscape that the Beaumont collection was richest, there being in it four small landscapes by Claude, one at least of surpassing beauty; others by N. Poussin; by Both (a capital example of his manner); by Rubens (the famous Balbi landscape, and, unlike most of Sir George Beaumont's pictures, of large size); by Canaletto; and by our own Wilson—the 'Niobe,' and the 'Villa of Mæcenas.' Among the other works was Wilkie's 'Blind Fiddler.' About the same time the British Institution presented to the nation the 'St. Nicholas,' of Paolo Veronese; the 'Vision of St. Jerome,' by Parmigiano; and West's 'Healing the Sick.' Mr. Zachary added a 'Spanish Boy,' by Murillo; and the Rev. W. Long the 'Banished Lord' of Sir Joshua Reynolds; whilst the government purchased for 3,800*l.*, a 'Holy Family,' by Correggio; and for 9,000*l.*, a 'Bacchanalian Dance,' by N. Poussin; 'Christ appearing to Peter,' by Annibale Carracci; and Titian's fine joyous 'Bacchus and Ariadne.'

Thus, then, the National Gallery was fairly launched. Its progress, however, was for a time very slow. Had it not been for bequests and presentations, it would not, indeed, have made any progress at all, no picture of any kind having been purchased between 1826 and 1834, when the Marquis of Londonderry's two superb Correggios (the 'Ecce Homo,' and 'Mercury instructing Cupid,') were bought for 11,500*l.* Before this, however, three or four valuable English pictures had been presented to the gallery (including the 'Holy Family,' of Reynolds, and the 'Market Cart,' of Gainsborough, the gift of the British Institution). Another fine work was Rubens's splendid 'Peace and War,' the gift of the Marquis of Stafford. But the most important addition was the noble bequest of the Rev. W. Holwell Carr in 1831, of no less than 35 pictures, all but one by the old masters, some of them being of a high class. For the next ten or twelve years bequests fell in rather rapidly, perhaps owing somewhat to the interest aroused by the building of the new National Gallery, which was commenced in 1832, and opened to the public in 1838. In 1837 the collection received an augmentation of 17 pictures, bequeathed by Lieut.-Colonel Ollney, mostly of small size, but of a class attractive to ordinary visitors; in 1838 it received 15 pictures, chiefly of the Dutch and Flemish schools, left by Lord Farnborough; and in 1846, 14 left by Mr. R. Simmons. The chief subsequent bequests, besides the two landscapes by Turner, left on condition that they should be placed in juxtaposition with two of the finest Claudes in the gallery, and the magnificent series of pictures, drawings, and sketches, which the great painter desired should form a separate collection, have been eight pictures bequeathed by Lord Colborne in 1854; three (a Giorgione, a Titian, and a Guido) bequeathed by the poet Rogers in 1857; and nineteen modern pictures bequeathed by Mr. Jacob Bell. The presentations during the same period have been chiefly of single pictures, and few of them have been of any remarkable value, with the exception of the collection of one hundred and fifty-seven pictures by English painters, the munificent gift of Mr. Robert Vernon.

Whilst, however, the vast importance of these bequests and gifts is fully acknowledged, it must be felt that it is upon the purchases that such an institution must mainly depend for the maintenance of a character worthy of the nation. Up to the time to which we have traced the purchases it will have been noticed that they were irregular, fitful, unsystematic. The principle adopted, as far as any principle was adopted, seems to have been to purchase any obtainable good paintings by the great masters of the best periods of the art in Italy and the Netherlands,—if the prices were not too high, and there were any money available for the purpose. Thus in 1837 three pictures were purchased for 9030*l.* (the 'Holy Family,' of Murillo; the 'Brazen Serpent,' of Rubens; and the 'Mercury and the Woodman,' of Salvator Rosa); in 1838, none; in 1839, for 7350*l.* three (one of them being the exquisite 'St. Catharine,' of Raffaele; the others, 'Holy Families,' by Garofalo and Mazzolini); in 1840, two; in 1841, three for 4300*l.* (two by Francia, and one by Pietro Perugino); in 1842 and 1843, one each ('Portraits,' by John Van Eyck of himself and wife (630*l.*), and an 'Apotheosis,' by Rubens); in 1844, six (including

Rubens's 'Judgment of Paris,' for which 4200*l.* was paid); in 1845, two; in 1846, two (one of them the 'Boar Hunt,' by Velazquez, for 2200*l.*); and in 1847, one (Raffaele's beautiful little allegory, 'The Vision of a Knight,' which was obtained for 1050*l.*). There then occurred an interval of three years without a purchase, partly owing, no doubt, to the disturbed state of political affairs during at least a portion of the period, but also to the discussions which had arisen respecting the general management of the gallery. In 1851 two pictures were bought (a 'Portrait of Rembrandt,' by himself, for 430*l.*, and a 'Portrait of a Man,' by Vandyck, for 365*l.*). In 1852, the only picture purchased was Titian's 'Tribute Money,' at a cost of 2604*l.* In 1853 two Spanish pictures were purchased from the collection of Louis Philippe—a 'Franciscan Monk,' by Zurbaran, for 265*l.*; and 'The Adoration of the Shepherds,' by Velazquez, for 2050*l.*; together with an 'Infant Christ,' of the school of Bellini, bought of Mr. Woodward for 500 guineas.

Up to this time the pictures purchased had continued to be almost exclusively such works of the painters commonly spoken of as the great masters, as were brought under the notice of the Trustees, and deemed by them suitable for the gallery. But in 1853 a new system was inaugurated. The inquiries instituted by the Commissioners of the Fine Arts, and the growing interest taken in all matters connected with early art, called forth a strong feeling in favour of the formation of a collection of early pictures, and the re-arrangement of the National Gallery on a chronological and historical basis. This view was adopted by a Select Committee of the House of Commons on the National Gallery, 1853, who embodied their views in a Report, the concluding passage of which recommended that "the funds appropriated to the enlargement of the collection should be expended with a view, not merely of exhibiting to the public beautiful works of art, but of instructing the public in the history of that art, and of the age in which, and the men by whom, these works were produced."

Effect was at once, to a certain extent, given to these views by the purchase, in 1854, of the collection of 64 early German works (but of which only 17 were retained for the Gallery, 10 being sent to the Dublin Gallery, and 37 sold by auction) belonging to Herr Krüger of Minden, and of some specimens of San Severino, Filippo Lippi, and other early Italian masters. But it was formally "embodied, leaving a due latitude to the trustees and directors, in the Treasury Minute dated 27th March, 1855, reconstituting the establishment of the National Gallery." (Report, 1858.)

By this reconstitution, whilst the Trustees were retained as the nominal superintending body, a superior salaried officer was appointed under the title of Director, to whom the selection and purchase of pictures for the gallery were intrusted, and on whom, in the words of the minute, was fixed "the final responsibility in all cases in which any difference of opinion may exist." Another new office created by the Treasury Minute was that of Secretary and Keeper, who was to rank immediately under the director, and to reside in the building as custodian of the pictures. The third office created was that of "Travelling Agent," who was to be a sort of assistant to the director in searching out among the pictures offered for sale on the Continent such as were suitable for the National Gallery. No material change was made in the inferior officers: instead of an occasional grant, there was to be inserted annually in the estimates for the National Gallery "a sum expressly for the purchase of pictures."

To the office of director was attached a salary of 1000*l.* a year. The gentleman appointed to that very important post—one on which the future rank and character of the gallery must mainly depend—was Sir Charles Lock Eastlake, the President of the Royal Academy, distinguished alike as an artist and as a writer on art. To the office of keeper and secretary—an office more laborious probably, and scarcely less onerous than that of director—a salary of 750*l.* a year was attached, and the government was fortunate in securing for the post the services of Mr. R. N. Wornum, a gentleman well known as a writer on the history of painting, and the lives of painters, and possessed of an unusually extensive acquaintance with pictures and with art-literature. Both these gentlemen have continued to hold their appointments to the present time. The travelling agent was to have a salary of 300*l.* a year, and an additional allowance for travelling expenses while absent on his professional duties on the Continent. To this office Herr Otto Mündler, a gentleman minutely acquainted with picture-galleries and old pictures, was appointed: the office was however abolished, in consequence of a vote of the House of Commons in 1858.

Under this new constitution the National Gallery made a very remarkable advance: not only were fresh pictures sought out and purchased, but the pictures already possessed were carefully examined, some covered with glass, others cleaned, or measures taken for their preservation, while of the state of all a most careful register was drawn up: the whole institution, in fact, was put into better working order, and subjected to a more searching and constant supervision.

The pictures purchased under the new régime have been of a very important character. In 1855 and 1856 twenty-six pictures were bought, but among these, and forming parts of collections, were seven which were not placed in the National Gallery; five being deposited in the National Gallery of Ireland, and two sold at Christie's with the Krüger pictures, under authority of an Act of Parliament (passed in June, 1856) which empowered the trustees and directors "to dispose of such

works as may have been purchased or bequeathed, but should be considered unfit or not required for a national collection;" thus enabling the authorities to deal for the purchase of collections of pictures with much more freedom than hitherto. Among the works retained, two were by Botticelli; one by Mantegna; one, an altar-piece grandly painted, and of very large size, by Paolo Veronese; one a 'Virgin adoring the Infant Christ,' a masterpiece of Pietro Perugino, obtained for 3571*l.*; the rest were chiefly by early Italian masters. But the new system was seen in its full flow in 1857, when no fewer than forty pictures were added to the collection by purchase. Of these the Lombardi-Baldi collection of early Italian (chiefly Tuscan) masters, comprised thirty-one pictures, and was obtained for 7035*l.* Other purchases were two pictures by Quintin Matsys, and one each by Lucas Cranach, John Van Eyck, Girolamo Romanino (an altar-piece in five compartments), and Borgognone; a Virgin and Child by Ghirlandajo, and the master work of Antonio Pollajuolo (for which the sum of 3571*l.* was paid)—all, therefore, early works, and especially valuable as illustrative of the historical progress of painting. But there was one picture purchased this year, the value of which was wholly different. This was the large and magnificent painting of the 'Family of Darius at the Feet of Alexander,' by Paolo Veronese, one of the most famous works of this great master, and, indeed, one of the most famous pictures in existence. It was purchased of the Count Pisani, for an ancestor of whom it was painted, and in whose family it had remained to the time of its purchase. Its cost was 13,650*l.*, a very large sum for a single picture; but it must be remembered that works of such a character are becoming constantly more difficult to procure, and consequently when any one is offered for sale, the agents of the various royal and national collections are eager competitors for its purchase, and the price is proportionately raised. Be the price as it may, this is unquestionably the most important single picture added to the gallery since its formation; and this, and the other pictures bought since the reconstitution of the gallery, are evidence of the advantages likely to accrue from a systematic search for works of a suitable character, rather than patiently waiting for them to offer themselves for approval.

During 1858, only eight pictures were bought, not exclusively, but still chiefly early works, the most important being a 'Deposition in the Tomb' by Marco Palmezzano, a 'Virgin and Christ' by Cima da Conegliano, another by Marco Basaiti, and portraits by Antony Moro and Moretto. In 1859 the purchases of the early masters were comparatively few. Eight pictures were bought in all: among them being a 'Pieta,' by Carlo Crevelli; a 'Madonna and Child Enthroned,' by Ireviso, and another by Lorenzo Costa; a pair of 'Landscapes with Waterfalls,' by Ruysdael (cost 2250*l.*); and 'The Infancy of Jupiter,' by Giulio Romano (cost 920*l.*). In 1860 was purchased, at a cost of 9205*l.*, the entire collection of M. Beaucousin, of Paris, consisting of 46 pictures, of which 35 were retained for the National Gallery, including small specimens by Ghirlandajo, Titian, Giulio Romano, Lorenzo di Credi, Bronzino, Roger Van der Weyden, and other noted masters of various schools—none of them works of the highest order, but several very desirable examples of the respective masters.

Thus after an existence of thirty-six years the National Gallery, exclusive of the Vernon and the Turner collections, comprises 420 pictures; of which 203 have been purchased at a cost of 184,500*l.* (in which however is included the 22 pictures placed in the Dublin National Gallery), and 217 presented or bequeathed. Of these 350 belong to foreign schools, and 70 are by British artists. The latter have been, for the most part, donations, and are hardly looked upon as belonging to the National Gallery, which by the trustees has always been regarded as specially devoted to the works of the old masters. The building known as the National Gallery is indeed entirely appropriated to the foreign schools; the British paintings, after having been for some years hung in Marlborough House, being now all removed—with the exception of the two landscapes by Turner, which, by the terms of the bequest, must be placed alongside two of the Claudes—to a building constructed for their reception contiguous to the South Kensington Museum.

In extent the national collection is far inferior to several of the other national collections of Europe, and even to some of the private collections in our own country. Mr. Wornum has, in his admirable official 'Catalogue of the National Gallery,' given from their respective catalogues the numbers of several of these collections. It will suffice to mention, for the sake of comparison, that in the Louvre there are upwards of 1800 paintings, of which 543 are Italian; the Dresden Gallery has 2000; the Museo of the Prado at Madrid, 1833; the Berlin Gallery contains about 1350; in the Belvedere at Vienna there are upwards of 1300; in the Imperial Gallery of Florence upwards of 1200; and in the new Pinacothek, Munich, about 1270. To the number in the Louvre might also be added the 3000 paintings at Versailles (to say nothing of those in the Luxembourg), all by native artists, and illustrative of events in the national history; as, on the other hand, to exhibit the extent of our own pictorial wealth, we might add to the National Gallery pictures, those in the Vernon, Turner, and Sheepshanks collections, numbering in all 490 paintings by British artists. If these collections were brought together, the National Gallery would comprise upwards of 900 pictures: or without the Sheepshanks collection, which perhaps cannot be reckoned a part of the National Gallery, it would number 670 pictures.

But looking at our National Gallery as a collection of paintings by the old masters, we may, whilst admitting its inferiority to the great continental galleries, regard its actual state with some complacency, consideration being had to the period of its formation, and the subsequent political and other circumstances which have interfered with its development. Taking the "Tabular View of the Schools of Painting as represented by the Pictures in the National Gallery" in the official catalogue as our guide, we find that although many of the more eminent painters of the several schools are unrepresented, or represented very inadequately, there are examples of the art, and for the most part, of the best period, of almost every school. Thus, adopting the classification of the 'Tabular View,' we find that there are of the Tuscan or Florentine school 57 examples; of the Umbrian, 6; of the Romagna 1; of the Roman, 17; of the Venetian, 50; of the Paduan, 3; Bolognese, 34; Ferrarese, 9; Parmese (Lombard), 7; Cremonese (Lombard), 1; Milanese (Lombard), 1; Neapolitan, 3; Greek or Byzantine, 1; Flemish, 35; Dutch, 44; German, 21; Spanish, 6; and French, 34.

As we have said, it was to the pictures of what is by common consent regarded as the best period of each school that the purchases of the trustees were until recently almost exclusively confined. But since the importance of obtaining works of the earlier and immature periods of the several schools has been recognised, very rapid progress has, as we have seen, been made towards supplying the deficiencies. And important as this chronological view of art unquestionably is, we may perhaps doubt whether any attempt to carry it into operation at an earlier date would have been altogether advantageous, or whether it may not even now be carried too far. The public required at first to have its interest in art aroused by means of pictures of such unquestionable merit that no one could gainsay their value, and of a kind which, by appealing to the common feelings and understanding of mankind, would require no special archaeological training to understand and to appreciate. In truth, there is already something a little bewildering to the common mind in the present almost heterogeneous admixture of the noblest works of art, at its highest stage of development and independence, with those produced when art was the mere instrument of the ecclesiastic, and artists, themselves as yet but feeling their way even to the technics of their pursuit, were hampered by archaic forms, conventionalities, and clerical symbolism and precedent. Such works can have little interest for the uninstructed visitor, and assuredly they can do little to refine his taste or elevate his thoughts. No lover of art will however object to the purchase of such works; but on the contrary, be most anxious that they should be purchased, their true value being clearly recognised. It is said in the Report for 1858 of the Director of the gallery in reference to the purchase of the Lombardi-Baldi pictures, that "the unsightly specimens of Margaritone and the earliest Tuscan painters, were selected solely for their historical importance, and as showing the rude beginnings from which, through nearly two centuries and a half, Italian art slowly advanced to the period of Raphael and his contemporaries." And this is precisely the reason for desiring similar pictures of every other important school. But there should be no exclusive or even preferential regard given to these works. Let them be bought for their archaeological value, but let the really great works of art be at least as anxiously sought for. Beauty is too rare and too precious a thing to be set aside for the sake of the "unsightly" antiquities whose chief charm is their age and their ugliness. And it is further of the first importance that, in exhibiting these early works to the public, this "historical" purpose should be distinctly pointed out, or we may only increase the confusion in uninstructed minds as to the true purpose of art, and as to what is really admirable in it. These very early works are not merely often unsightly, but they are (to modern and Protestant eyes) not unseldom profane, and sometimes gross. Their unsightliness, profanity, and grossness, are, of course, of no consequence to the historical inquirer and the art-student, but these are qualities not to be wholly overlooked in catering for the great public. The chronological and the geographical arrangement of all the works of this antiquarian character ought to be strictly maintained. The truly great works—those which are really works of fine art—should not be buried amidst the uncouth, unsightly church-decoration work of the pre-fine-art ages. A strictly chronological and geographical arrangement of *all* the works, however it might satisfy a formal spirit of systematism, or accord with the fashionable mediævalism, would assuredly be very wearisome if not misleading to the general public. The early works, in short, are for the historical student; the master-works for all.

Of course any chronological arrangement according to schools is impracticable in the present National Gallery. The building, which was erected from the designs of Mr. W. Wilkins, R.A., was only completed in 1838, yet that portion of it appropriated to the national collection of pictures is already so crowded—though it contains only the comparatively small collection of paintings by the old masters—that many works are necessarily hung in the passages and vestibule, and space has only been found for the display of recent acquisitions by means of screens placed in the centre of the great room. For the British pictures, rooms have been provided at South Kensington, but no spare space is left in them for relieving the overcrowded National Gallery of any foreign works, nor consequently do they afford any

suitable room for the reception of new purchases or presents. Successive governments have however, pledged themselves to provide adequate accommodation for the national collections. To do this, various schemes of a more or less official character, for altering and enlarging the existing building, have been projected by the director, Sir Charles Eastlake; by Captain Fowkes, the designer of the galleries at South Kensington; and on a more magnificent scale by the late Sir Charles Barry. The only sufficient remedy if the present site be retained, would be the removal of the present most ungainly, inconvenient, ill-lighted, and utterly inappropriate building, and the construction in its place (the barracks, &c., at the rear being included in the site) of one of sufficient size to contain in two great divisions—Foreign and English—all our national pictures, and to admit of their arrangement in a convenient and systematic manner. But a far better plan, if indeed it be not too late so to appropriate the site—incomparably more suitable for the pictures, and hardly at all less convenient to the public—would be the construction on the site of Burlington House of a grand National Gallery; which,—from the almost indefinite capability which the site affords for extension with the growth of the gallery,—might be at once designed, as such a gallery ought to be, to include a systematic collection of English as well as foreign pictures, and English as well as foreign sculpture, and also afford room for a National Collection of Water Colour Paintings, and the National Portrait Gallery: in a word, be a really comprehensive National Gallery of Art, worthy of the country. Of this there is little probability. It is, however, admitted by all that the time has arrived when some provision must be made for the growth of the collections, and it is understood that the Government has decided to carry out a plan prepared by Mr. Pennethorne, for the extension of the present building, though only as a temporary expedient.

Gallery of British Art: Vernon Collection.—As we have seen, there were included in the Angerstein collection, which formed the basis of the National Gallery, seven paintings by Hogarth, one by Reynolds, and one by Wilkie; and among the Beaumont pictures, five were by British painters. There was thus provided, at the very origin of the National Gallery, the germ of a Gallery of British Art. It would seem that one of the most obvious duties of the trustees would be to watch over and cherish the growth of the native section of the institution, with at least as much care as the foreign. But native art was resolutely discountenanced. It is a remarkable fact, that every additional specimen of English art which the nation possesses has been obtained by what may be called chance. Except the nine works which were included in the Angerstein collection, purchased six-and-thirty years ago, not a single English picture has, up to the present hour, been purchased for the national collection. Every one which the nation possesses has been either a gift or a bequest. Such a thing is probably unparalleled in any other country possessing a collection of pictures; but it arose from the entire control of our National Gallery being vested in gentlemen who regarded the Old Masters as the only legitimate representatives of painting. From the first they resolved that from the British National Gallery, British art must be excluded. Such works of Hogarth, Reynolds, Wilson, Gainsborough, and Wilkie, as were given or bequeathed they could not, of course, actually refuse to admit; but even to them they only accorded a contemptuous shelter. That any approach whatever has been made to a collection of works of British art is in no wise due to the trustees of the National Gallery, or to the British government, but solely to the patriotism and the benevolence of private individuals.

After having been in existence twenty-four years, the National Gallery possessed 44 British pictures, of which 35 were gifts. Of these several were common-place portraits. The ignorance, and the contemptuous indifference of foreigners respecting British art, has often been complained of; but how could foreigners be expected to take any pains to acquaint themselves with what was treated with such supreme neglect at home? If British art were worth anything, it might fairly be supposed that the nation would not keep it so carefully out of sight. The effect of a public collection of the works of the leading English painters in correcting the low opinions prevalent of British art was well shown in the Manchester Exhibition of 1857. The great French painter Ary Scheffer we are told, "was scarcely less astonished than enchanted with the spectacle which that collection afforded him. 'I had no conception,' said he, 'how rich the English school was! There have lived great painters among you; that is unquestionable! . . . The power of dealing with colour, especially, possessed by the English artists, fills me with admiration, &c.'" (Mrs. Grote's *Life of Ary Scheffer*, p. 117). And what Scheffer felt was felt more or less by every one, native as well as foreigner, who visited that remarkable collection.

The first actual attempt to provide a permanent gallery of national art was made in 1847, when Mr. Robert Vernon presented to the country his collection of 157 pictures, all but two being by British painters. For the most part the pictures were of a cabinet size, of homely and familiar subjects, and by living or recently deceased painters; though among them were 3 small works by Reynolds, 4 each by Wilson and Gainsborough, and 1 by Romney. Of our more eminent masters of a later date, the Vernon gift included 6 specimens by Stothard; 5 by Wilkie (all of second-rate quality); 6 by Hilton; 9

by Callcott; no less than 11 by Etty; 4 by Turner; 1 by Constable; 2 by Collins; 4 by Mulready; 3 by Eastlake (including two of his best works—'Christ Lamenting over Jerusalem,' and the 'Escape of the Carrara Family'); 2 by Leslie ('Uncle Toby and Widow Wadman,' and 'Sancho and the Duchess'); 4 by Stanfield; 2 by Roberts; 2 by Lee; 7 by Sir Edwin Landseer (including his large picture of 'Wellington at Waterloo,' 'High and Low Life,' 'Peace and War,' 'Highland Music,' &c.); 2 by Maclise (the 'Play Scene in Hamlet,' and 'Malvolio and the Countess'); 2 by Webster ('Going to School,' and the 'Dame's School'); 2 by Newton; 3 by Lance; 2 by Ward; and others by Creswick, T. S. Cooper, Bonington, Müller, Danby, Linnell, Uwins, Herbert, &c. They were pictures purchased by a private gentleman of plain tastes, for the decoration of a private house of moderate size. They were, therefore, not works of a kind that would, either in respect of size, subject, or pretension, have been chosen for a public gallery; but strictly cabinet or parlour pictures—pictures for quiet home enjoyment. Their presentation to the nation was an afterthought. While, therefore, they may be taken as very fairly representing the popular phase of British art, they are not to be received as adequately representing the school in its highest efforts, or even what it has actually accomplished. But though not great works, the collection included specimens—and most of them very excellent specimens—of the major part of the more eminent painters of Mr. Vernon's day. In short, it was a very admirable private collection; and it formed, in truth, a noble gift—so noble a gift, indeed, that it ought to have stimulated the nation, or its rulers, vigorously to carry on and complete the formation of a gallery of native art, so large an addition having been made to the means already possessed for the accomplishment of that object. Nothing, however, was done even towards providing a suitable place for the reception of so munificent a gift. Mr. Vernon's donation took effect during his lifetime, and the pictures were in the first instance exhibited to the public in his house in Pall Mall. From thence they were removed to the vaults underneath the National Gallery; and in 1850 they were taken to Marlborough House, where they remained till 1859, when that building was required for the residence of the Prince of Wales. A brick building was then erected for their reception adjoining the South Kensington Museum, and opening into it. It comprises seven spacious and well-lighted rooms, in which are hung the whole of the British pictures belonging to the National Gallery. One addition only, but that a worthy one, has been made to the British pictures in the National Gallery, since the gift of Mr. Vernon. This was the bequest in 1859, already referred to, of 19 pictures by Mr. Jacob Bell. Among these pictures are seven by Sir Edwin Landseer—including some of his best works—'The Defeat of Comus,' 'Sleeping Bloodhound,' 'Dignity and Impudence,' 'Highland Dogs,' 'Shoeing,' 'The Maid and Magpie'; Leslie's 'Uncle Toby and Widow Wadman'—being the third copy of this picture now possessed by the nation; Ward's 'James II. receiving news of the landing of the Prince of Orange'; three pictures by Charles Landseer; and one each by Etty, Lee, Cooper, Douglas, and G. O'Neill; also Frith's 'Derby Day' and Rosa Bonheur's 'Horse Fair,' though the last two, as well as one of Landseer's, are at present retained for engraving by the purchasers of the copyright.

The placing of these pictures at South Kensington is, however, only a temporary arrangement: suitable provision is to be made for the British pictures in "the new premises," which the government have undertaken to provide for the national collections. When that shall be done, we trust that so opportune an occasion will not be let pass without undertaking the formation of a Gallery of British Art worthy of the name. It is a mortifying fact, that the Collection of British Pictures at Manchester was the first and the only opportunity Englishmen have ever had of seeing at one view what the British school has done and is doing. That collection is dispersed, but the example remains. We have here, in the 70 pictures belonging to the National Gallery, and in the 150 of the Vernon collection, a good groundwork for a national collection. The Sheepshanks pictures were expressly given to assist in the formation of a gallery of native art, but the gift was hampered with a clause as to the locality, which may render it unsuitable for that purpose. If that could be got over, they would be of the greatest value, and they would render tolerably complete the series of recent works of their class. The century of Turner landscapes are a specialty, and will in any gallery occupy their own apartment. But together we have thus 560 paintings by British artists, some 520 of them having been presented to the nation for the express purpose of assisting in the formation of a British gallery. In a few years Sir Francis Chantrey's bequest of above 2000*l.* a-year for a like purpose will fall in. If such a gallery were really taken in hand with an evidently sincere desire of making it what it ought to be, there can be no doubt that other gifts and bequests would not be wanting. All that would be required of the authorities, in addition to a suitable building, would be to see that the great object was kept steadily in view of making a thoroughly comprehensive collection of characteristic works. To this end suitable early pictures, and pictures of a high class, should be sought out and purchased, and for the present, at least, purchases should be strictly confined to works which fairly illustrate the rise and progress of British art. And surely if it be desirable to secure "unsightly" early examples of the Italian and German schools "solely for their historical

importance," it is at least as important to Englishmen, even in an historical point of view, that they should possess a systematised chronological collection of works of the British school, beginning at the very beginning, and including the very noblest of its productions.

Turner Pictures.—During many of the last years of his life, the cherished wish of our great landscape-painter was to bring together as many as possible of his best works as an offering to his country. For this purpose he not only refused to sell such of the pictures he then painted as he deemed most suited for a public gallery, and most illustrative of his style, but, whenever an opportunity presented itself, purchased such of his earlier paintings, having like fitness, as were offered for sale. At his death, in 1851, he bequeathed to the nation these works, together with all his drawings and sketches, on condition that within ten years suitable accommodation should be provided for them. This princely gift—for, estimated merely at the money value according to the almost fabulous prices his pictures and drawings were then producing, the gift might without exaggeration be termed princely—comprised the extraordinary quantity of over a hundred finished paintings in oil, many of them of very large size, some hundreds of finished water-colour drawings, and several thousand studies and sketches.

The oil paintings and some of the sketches are exhibited in the new rooms at South Kensington. Of their value as works of art, it would be superfluous if it were not out of place to speak here. Alone, they would suffice to give the British school of landscape the foremost rank in respect of extent of range, comprehensiveness of subject, and poetic conception along with close observation of nature. As illustrative of the genius of Turner, it is enough to say, that they were deliberately chosen by Turner himself as the works by which he wished his countrymen and the world to judge him. They range over almost the whole of his career, and exhibit almost every phase of his style, from the strictest and most literal representations, up to his most daring imaginations. If they needed to be supplemented by others, we have in the National Gallery, the Vernon, and the Sheepshanks collections, eleven more of his oil pictures. But they are sufficient in themselves. Of the works of no other English painter are we ever likely to have anything like so large or so wonderful a gallery, or one so remarkably illustrating the progress of the mind of a great artist. It is only to be regretted that the drawings are not to be exhibited to the public as well as the paintings. These drawings, which when received by the trustees were in a very crushed and disorderly condition, have been carefully examined and arranged, and 400 of the most highly finished of them framed, and 1200 more mounted by Mr. Ruskin, who voluntarily undertook that troublesome task. They are, with the exception of those exhibited at South Kensington, deposited in cabinets in one of the lower rooms of the National Gallery.

The Sheepshanks Pictures.—The noble example of Mr. Vernon was in 1857 nobly followed. On the 2nd of February of that year, Mr. Sheepshanks, by a deed of gift, presented to the nation his valuable collection of paintings and drawings. The object of the gift, as stated in the deed, was the foundation of a "collection of pictures and other works of art fully representing British art." The gift was made on certain conditions, the most important of which was that "a well-lighted and suitable gallery, to be called the 'National Gallery of British Art,' shall be at once erected by her Majesty's government, and be attached or near to the public buildings built or to be built for the Department of Science and Art on the estate purchased by her Majesty's Commissioners for the Exhibition of 1851, or the public parks or gardens at Kensington." The collection is thus precluded from being united with that of Mr. Vernon and with the British pictures belonging to the National Gallery, unless these should also be permanently removed to Kensington. But Mr. Sheepshanks, so far from wishing his pictures to be kept apart from others, has expressly provided that they are to "be deposited in such gallery with any other pictures or other works of art that may be subsequently placed there by other contributors, as it is not my desire that my collection of pictures and drawings shall be kept apart, or bear my name as such." Further, Mr. Sheepshanks stipulates that "none of the said pictures or drawings shall ever be sold or exchanged," and he has placed them entirely beyond the control of the trustees of the National Gallery. They are vested solely in that member of the government, for the time being, "charged with the promotion of art education now undertaken by the Department of Science and Art." Finally, if these "terms and conditions be not strictly adhered to," the pictures and drawings are to be transferred to the University of Cambridge, "and for ever after to form part of the Fitzwilliam Museum."

These conditions were fully acceded to by the government. A convenient and well-lighted brick building, and one admitting of easy extension, was erected adjoining the iron Museum of Ornamental Art at South Kensington, and opened to the public in June, 1857. The rooms in which the Vernon pictures are now hung adjoin these, and the two galleries open into each other. Like the Museum of Ornamental Art, these rooms are open to the public free on Monday, Tuesday, and Saturday during the day, and on Monday and Tuesday evenings; and on the other three days and Wednesday evening on the payment of sixpence—rather a curious arrangement in a national institution, and one that we may hope will not be followed when

the British and foreign pictures are re-united in the National Gallery.

The collection of Mr. Sheepshanks, like that of Mr. Vernon, was formed for a private house, and consists therefore entirely of cabinet-sized pictures. Far more than the Vernon collection, however, is it characteristic of the taste of the founder. Mr. Sheepshanks evidently bought and commissioned pictures only in accordance with his own personal likings. Even more exclusively than Mr. Vernon's does it consist of genre and landscape-paintings. The examples of historical or purely imaginative works are extremely few. But in its way the collection is an admirable one. It comprises no fewer than 234 oil-paintings, ranging over a period of about 50 years, and embracing very choice examples of many of the most eminent painters of the time.

Especially is it rich in the works of Mulready and Leslie, some of whose best pictures are here; but it is rich, also, in the works of Landseer, Wilkie, Stothard, and Webster. Of Mulready there are no less than 34 examples, the earliest painted in 1806, the latest in 1848. Some of these are very small, and comparatively unimportant: but among them are his famous 'Choosing the Wedding Gown'—one of the gems of British art; his very beautiful 'Sonnet,' and 'First Love'; the popular 'Giving a Bite,' the 'Fight Interrupted,' and the 'Butt—Shooting a Cherry,' three of his most humorous works; his most elaborate though not his most successful picture of 'The Seven Ages'; and his interesting 'Interior, with a Portrait of Mr. Sheepshanks.' By Leslie there are 24 paintings, the dated ones extending from 1823 to 1845. The best of them are his illustrations to Shakspeare, Molière, and Sterne, of whom he gives always a genial, often a suggestive reading, and one marked by a quiet refined humour: it will be enough to name the 'Katherine and Petruchio,' 'The Dinner Scene from the Merry Wives of Windsor,' 'Queen Katherine and Patience,' 'Florizel and Perdita,' 'Autolycus,' 'Le Bourgeois Gentilhomme,' 'Les Femmes Savantes,' 'Le Malade Imaginaire,' and the popular rendering of 'Uncle Toby and the Widow Wadman.' By Landseer there are 16 paintings, of which the dates extend from 1814 to 1842; and we may notice, in passing, that among the drawings presented by Mr. Sheepshanks are some of special interest to the admirers of our great animal painter, being some of his very earliest pen and pencil drawings and sketches,—almost unique examples of precocity in fact,—a 'Hound,' for example, inscribed "drawn at five years of age," a 'Calf,' "drawn by E. L. when he was first breeched," a 'Head of a Bull,' and a 'Group of a Sow and Pigs,' "drawn from nature at the age of eight years and two months," and so on. The largest of Landseer's paintings here (and one of the largest pictures in the collection) is the 'Drovers' Departure—scene in the Grampians,' one of his most characteristic and elaborate works, widely known by Mr. Watt's admirable line engraving. Among his other pictures are the 'Highland Breakfast,' 'The Old Shepherd's Chief Mourner,' 'There's no Place like Home,' 'The Two Dogs,' 'Jack in Office,' and one or two more in which not only his power, unrivalled among living painters, of representing the form, clothing, and expression of animals, is fully displayed, but also his humour and his pathos. By Turner there are five pictures, all but one English—the 'Vessel in Distress off Yarmouth,' 'Line-Fishing off Hastings,' 'St. Michael's Mount, Cornwall,' 'East Cowes Castle,' and 'Venice.' By Wilkie there are six pictures, but only one of any value, 'The Refusal—Duncan Gray,' and that, we are told in the official catalogue, "was in a most dilapidated state from the use of asphaltum, but has been repaired by Mr. Bentley." The six pictures by Webster are all good examples of that painter's genius: among them are the excellent companions painted in 1838—'Going to the Fair,' and 'Returning from the Fair'; 'The Village Choir'; and 'Sickness and Health.' By Stothard there are 10 paintings, including several of his Shakspeare pieces, 'Sancho and the Duchess,' 'Sir Roger de Coverley and the Gipsies,' and two of his most humorous efforts—'John Gilpin' and 'Tam o' Shanter.' Further, there are 9 examples by Collins, 6 by Constable, as many by Redgrave; 3 each by Stanfield, Roberts, Lee, and Danby; 2 each by Etty, Eastlake, and Creswick; 9 by Calcott; 11 by Cooke; 9 by Cope; 4 by Uwins, and so on. The drawings, which are varied and interesting, are exhibited in a room adjoining those which contain the oil-paintings. Among them are some fine drawings by Turner, Prout, &c., but the greater part are sketches and studies. To these has recently been added a small collection of drawings in water colours, the gift of Mrs. Ellison, which is valuable not only in itself, but as serving as the nucleus of a comprehensive collection of works in that essentially British line of art.

The National Portrait Gallery, though an entirely independent institution, will be conveniently noticed here. The importance of forming a gallery of portraits of eminent Englishmen had long been insisted on by historical students before it attracted much public interest or the notice of the government. But thanks mainly to the zealous and persevering advocacy of Earl Stanhope (then Lord Mahon), the subject was at length listened to. The Houses of Parliament gave a favourable response to a direct appeal, the government proposed a grant for 2000*l.*, and the Gallery became a reality. By a treasury warrant dated December 2nd, 1856, a "board of trustees for the National Portrait Gallery" was appointed, and early in 1857 the machinery was got into operation, Mr. George Scharf, a gentleman best known to the public by the admirable outlines with which he has enriched many valuable works, but known also to art-students as one

of the most accomplished of living English art-critics and archæologists, being appointed secretary and keeper—the real working officer of the institution. By the end of the year, not only had the whole been got into good working order, but 23 portraits had been hung on the walls of the temporary apartments assigned by the government to the collection in 29 Great George Street, Westminster. Of these portraits, 15 were purchased, 8 were donations. Up to the present time (August, 1860) 74 more portraits have been added. Of the 97 portraits now in the gallery, 62 have been purchased and 35 donations.

In the commencement of their work the trustees were singularly successful: the foundation-stone being laid by the Earl of Ellesmere, in the presentation of the famous Chandos Shakspeare—which the Earl had purchased at the Stowe sale in 1848 for 355 guineas; and the purchase by the trustees of a characteristic portrait of 'Sir Walter Raleigh,' the picture mentioned by Aubrey, who saw it at Downton, where it remained till its removal to the National Portrait Gallery.

As little is generally known of the state of the gallery, we will enumerate its contents, noting separately the presents and the purchases, and commencing with the former. Following Shakspeare in order of time was a portrait of William Wilberforce, by Sir Thomas Lawrence—a picture left unfinished by the painter, the head, a very forcible one, being alone completed; Viscount Sidmouth, a water-colour drawing by G. Richmond; Spencer Perceval, painted by Joseph, from a mask taken after his assassination, and wearing a somewhat death-like but kindly expression: these three portraits were all bequests by Sir R. Inglis. James, first Earl Stanhope, the distinguished statesman, by Sir Godfrey Kneller, presented by the present earl. Thomas Stothard, R.A., by James Green, presented by Mr. J. H. Anderdon—a good likeness, as may be supposed from its having belonged to his friend the poet Rogers, at whose sale it was purchased by Mr. Anderdon. The poet Thomson, by Paton, "more fat than bard beseems," and heavy-eyed withal. George, first Viscount Torrington, painted by Sir Godfrey Kneller, and presented by the present viscount. John Foxe, the martyrologist, painter unknown, presented by the Society of Antiquaries. Wright of Derby, painted by himself—a second-rate painter, but a cheerful, intelligent-looking man—presented by Mr. W. M. Rossetti. The sculptor Nollekens, painted by F. Abbott, leaning on his favourite bust of Fox, and holding his sculptor's tools in his hand, presented by Mr. Labouchere. Sir Francis Burdett, by Phillips, a good likeness, presented by his daughter. Lord Chancellor Talbot, by Richardson, presented by the Hon. Mrs. J. Talbot. The well-known portrait of Sir James Mackintosh, in his robes as Recorder of Bombay, painted by Sir T. Lawrence in 1803, presented by the son of Sir James. Robert Burns, also well known by the engraving, here ascribed to Nasmyth and Raeburn: it formerly belonged to Burns's friend and publisher, George Thomson, and was presented by Mr. J. D. Dillon. John Philip Kemble, by Gilbert Stuart; and his sister, Mrs. Siddons, painted by Sir William Beechey, in 1798: both these were presented by Mr. J. T. Delaine. An excellent head, by Reynolds, of the celebrated Earl of Shelburne, and first Marquis of Lansdowne, presented by the present marquis. An intelligent and characteristic, though somewhat faded portrait, by Reynolds, of old Admiral Boscawen, presented by Viscount Falmouth. A profile portrait (artist unknown) of General Wolfe, formerly the property of the Princess Charlotte, presented by the King of the Belgians. A miniature of Athenian Stuart, presented by his son. Keats the poet, painted by his friend Severn, and presented by Mr. Travers. President Forbes, of Culloden, presented by Sir John Forbes. Dr. Edward Jenner, by Northcote, presented by Mr. J. C. Moore. Dr. Nathaniel Hooke, presented by Lord Boston. Sir Charles Bell, presented by his widow. John Knox, the gift of the Duke of Buccleuch. James Gillray, the caricaturist, painted by himself, the gift of Col. Bagot. Sir Stamford Raffles, given by his nephew. The Rt. Hon. Thomas Winnington, presented by Sir Thomas Winnington. Sir Francis Chantrey, painted by Phillips, presented by Lady Chantrey. The Seventh Earl of Derby, presented by the present Earl. Matthew Prior, painted by Richardson, presented by the Earl of Derby. Sir Leoline Jenkins, presented by the Rev. J. M. Treherne. And lastly, a medallion by Chantrey, of Henry Kirke White, presented by Dr. Boot.

As will be seen, though with two or three exceptions not of our greatest men, nor of the highest order of pictures, the donations are of an exceedingly interesting kind. But it is manifest that it is upon the purchases that reliance must be placed for keeping the collection up to the mark. All that the trustees can do as regards donations, is to decide whether the person represented has a title to a place among British worthies, and whether the portrait is authentic; and to accept or decline it accordingly. To guard against improper admissions "three-fourths at least of the trustees present at a meeting must approve" of any donation. The purchases, on the other hand, test at once the fitness and the diligence of the trustees. Had the gentlemen selected as trustees been merely "distinguished patrons of art," habitués of the picture galleries, the spirit of dilettantism would have led them far astray before they could have been checked by public opinion. But among them were included politicians of all parties, historians, antiquaries, artists, and connoisseurs. The original trustees were—The Lord President of the Council for the time being; the Marquis of Lansdowne; Earl Stanhope; Earl of Ellesmere; Lord

Elcho; Right Hon. Sidney Herbert; Right Hon. B. Disraeli; Lord Robert Cecil; Lord Macaulay; Sir Francis Palgrave; Sir Charles Eastlake, P.R.A.; William Smith, and W. H. Carpenter, Esqrs. On the death of the Earl of Ellesmere, in 1857, Mr. Thomas Carlyle was appointed to supply the vacancy; and on the death of Lord Macaulay the vacancy was filled by the election of Mr. Gladstone. As might be expected, therefore, there has been no partisan or sectarian exclusiveness in their selections. The first regulation which the trustees laid down for their guidance was "in either making purchases or receiving presents, to look to the celebrity of the person represented rather than to the merit of the artist. They will attempt to estimate that celebrity without any bias to any political or religious party. Nor will they consider great faults and errors, even though admitted on all sides, as any sufficient ground for excluding any portrait which may be valuable as illustrating the civil, ecclesiastical, or literary history of the country." The second that "No portrait of any person still living, or deceased less than ten years, shall be admitted by purchase, donation, or bequest, except only in the case of the reigning sovereign, and of his or her consort, unless all the trustees in the United Kingdom, and not incapacitated by illness, shall either at a meeting or by letter, signify their approbation."

These were their rules, the following are their purchases. The Raleigh we have mentioned. The next purchase was Handel, by Hudson (the master of Reynolds), the great composer being represented in full dress, with gold lace and ruffles—the dress he used to put on when he sat down to compose a work of more than usual grandeur. Dr. Parr, by Dawe, a rough, course head, bought of Parr's nephew. Arthur Murphy, by Dance. The Speaker Lenthall, from Burford Priory, the seat of the Lenthall family. Horne Tooke, by Hardy. Mead, the physician, by Allan Ramsay, 1740. Robert Harley, first Earl of Oxford, by Sir Godfrey Kneller. Sir William Wyndham, by Highmore. The first Earl Cadogan, by Laguerre. Richard Cumberland, by Romney. La Belle Hamilton, a copy by Eckardt from Lely, which might very well have been left unpurchased. William Huskisson, by Rothwell (1831). Archbishop Wake, probably by Gibson. Bishop Warburton, by C. Phillips: by the way there are at Hampton Court two portraits of a brother prelate, Hurd, whose name is indissolubly associated with Warburton's, one of which might well be sent to renew the companionship here. William Sharp, our best portrait engraver, by Lonsdale. Our great circumnavigator, Captain Cook, painted by John Webber, R.A., who accompanied him as draftsman. Sir William Chambers, the architect, by Reynolds. Elizabeth Carter, the Greek scholar, a crayon drawing by Lawrence. Bishop Hoadley, by Mrs. Hoadley, but, as is believed, touched on by Hogarth. Cardinal Wolsey, a profile formerly at Weston, Warwickshire. General Ireton, by Walker, a stern, grave face admirably painted—from the Lenthall collection. William Pulteney, Earl of Bath, by Reynolds, but sadly faded. Sir William Windham, a fine manly head, by Lawrence, an early work, and more solidly painted than his later pictures. Theodore Hook, by Eddis. Sir Ralph Winwood, a very characteristic head, by Mirevelt—engraved by Vertue. Nell Gwynne, by Lely. The Princess Charlotte, by Dawe, the first of the many portraits which he painted of the princess, and retained by him till his death. Lord Clive, by Dance: the calm decision of the great commander well marked. Sir Joshua Reynolds, painted by himself before his visit to Italy, and consequently before the injury to his lip, which gives so peculiar an expression to his face in subsequent portraits: in all respects an admirable painting, as a work of art one of the very finest in the collection. Sir David Wilkie, a small but characteristic head, painted by himself at the age of twenty-nine. John Opie, R.A., painted by himself at the age of twenty-four—of no great value as a painting, but with the others serving as a good foundation for a series of portraits of British painters. Henry Wriothesley, Earl of Southampton, the friend and patron of Shakspeare, by Mirevelt (or, as we fancy, by Mytens). Judge Jeffreys (as Recorder of London), by Kneller. John Dryden. William Harvey, the discoverer of the circulation of the blood. George Colman, by Gainsborough. James I., when a child. Sidney's Sister—Pembroke's mother, so at least it is described in the catalogue, on what authority it is not stated, and the ascription is very far from satisfactory. William Powlett, first Marquis of Winchester. Antony Ashley, first Earl of Shaftesbury. Congreve, by Kneller. Sir Robert Walpole, by Vanloo. Elizabeth of Bohemia, by Janssens. Lord Nelson, painted at Vienna in 1800, by H. Füger. Abraham Cowley, by Mr. Beale. Earl Howe, by Singleton. John Selden. John Hunter, a capital copy, by Jackson, of the celebrated portrait by Reynolds—now a ruin. James, second duke of Ormond. The Seven Bishops, painted immediately after their acquittal. John Smeaton, with the Eddystone lighthouse in the distance. Warren Hastings. David Garrick. James Watt, by De Breda. Dr. Darwin, by Wright of Derby. Sir M. I. Brunel, by Drummond. Archbishop Tillotson, by Mrs. Beale. William Huntington—Sinner Saved. Sir William Herschel, by Abbot. Mary Queen of Scots. And finally, John Howard.

We have gone through the entire list of portraits in the gallery up to August of the present year. To them is however to be added, Hayter's large picture of the 'First Reformed House of Commons,' which was purchased by the government on the recommendation of a Committee of the House of Commons, in order to add to the National

Portrait Gallery. Its claim to a place in this gallery arises from its containing a large number of the leading politicians whose names are associated with the Reform Act, and other important measures which have acquired an historical interest. But we may regard the admission of this picture as important chiefly as forming a precedent for the introduction of a most valuable class of works, those namely which are strictly contemporary representations of historical scenes or circumstances, instead of exclusively restricting the gallery to portraits; though this should be the only deviation permitted.

This list will have shown that an excellent commencement has been made in the formation of a National Portrait Gallery. Many of our greatest names are wanting, and the trustees have been censured for purchasing portraits of second or third-rate men, while there are no portraits of Bacon, Newton, Milton, and others of the highest order. But it must not be forgotten that authentic portraits of such men are, as has been said, almost as difficult to meet with as the men themselves; and the trustees appear to be fully alive to the importance of securing the portraits of our greatest men. An annual grant of 2000*l.* is made for the purposes of the gallery; but the trustees, desirous of availing themselves of opportunities for large acquisitions by "a sale at some great country-house, or a dispersion of some celebrated collection," do not expend this sum unless portraits of unquestionable importance offer. On the whole, there can be little hesitation in acknowledging, on looking through the list of their purchases, that the trustees have acted up to the spirit of the rule they laid down for their guidance, and that the selection has been made in a liberal and comprehensive spirit. At present the pictures are placed in apartments in a private house, No. 29 Great George Street, Westminster, which barely afford room for those already obtained, and are most unsuitable for their public exhibition. Until sufficient room is obtained no attempt can be made to arrange the portraits in any chronological order or series. When adequate room is provided we may hope to see added to them at least a selection from the British portraits now hung out of sight over the stuffed birds in the British Museum. In the National Portrait Gallery, portraits of Queen Elizabeth, Oliver Cromwell, William the Third, Cranmer, Drake, Algernon Sidney, Marlborough, Bacon, Newton, Locke, Pope, and the like, would find a fitting home and associates; whereas nothing can possibly be more inappropriate than their present locality. It cannot be said that these portraits are inalienable or irremovable, for in the National Gallery there is at least one portrait "deposited by the Trustees of the British Museum," and that of one (Sir William Hamilton) who, from his connection with one of the collections in the British Museum, it might have seemed especially desirable to retain in that institution. And why might not the British Portraits in the National Gallery be also transferred to the National Portrait Gallery? Among them are several of considerable interest on account of the persons represented, yet of but inferior consequence as works of art. The property in these portraits might of course be retained by the respective trustees, although united in this gallery. If this were done, a noble National Portrait Gallery might be at once opened, and owners of the portraits of eminent British worthies would soon be found eager to add their contributions to the national collection.

Hampton Court.—There remain two other galleries which, though not strictly, are virtually national—those at Hampton Court Palace, and Greenwich Hospital. The paintings at Hampton Court are the property of the crown, and the bulk of them are those which have been removed here from the other royal palaces. In all they are no less than 1850 in number. For the last twenty years the whole of the state apartments, in which the pictures are hung, have been thrown openly freely to the public. The grand feature of the collection is the unrivalled series of seven Cartoons of subjects from the Life of the Saviour and the Acts of the Apostles, by Raffaele, which are by universal consent admitted to rank as the noblest works of their class in the world. They have until lately been seen to great disadvantage in the room built expressly for them by Sir Christopher Wren. But recently they have been lowered considerably, to the manifest improvement of their appearance. It has also been deemed advisable to cover them with glass, which however, whatever may be said on the score of security, can hardly be commended as adding to their beauty.

Next in importance to Raffaele's cartoons are those by Mantegna of the 'Triumphs of Julius Cæsar,'—a series of nine large grandly executed coloured drawings, but unfortunately in a sadly dilapidated condition. The collection of oil-paintings is of the most miscellaneous character possible. It includes specimens of every variety of merit and demerit attributed to painters of almost every age, school, and grade, from Francia and Raffaele, Sebastian and Michel Angelo, Mabuse and Holbein, Titian and Tintoretto, Vandyck and Vandevelde, Lely and Kneller, Gainsborough and West, down to Parcelles and Huggins. It is needless to repeat what has been a thousand times said, that the correct attribution of great names is the exception here. But as the gallery is opened for public instruction, it is much to be regretted that a thorough re-examination of the entire collection, with the aid of such documentary evidence as may be in existence, is not made, and what is then believed to be the true name of the painter affixed to every picture which it is deemed advisable to retain for public

exhibition. A large amount of rubbish—worthless alike in an artistic and an historical point of view—might well be consigned to oblivion. Such a re-examination would permit of two things—each important in its way. First, the formation of a comparatively small collection of paintings valuable as works of art; and next, of a collection of portraits and contemporaneous delineations of historical occurrences of singular value and interest. The really authentic portraits here probably number some hundreds; and they include many by Holbein of Henry VIII. and members of his family and court; others of almost all our monarchs down to George III., including several remarkable ones of Mary, Elizabeth, and the first James, one of the duplicates of Vandyck's grand equestrian portrait of Charles I., and a large and most ambitious equestrian portrait of William III., by Kneller. Then there is Sir Peter Lely's famous series of the 'Beauties of the Court of King Charles II.' and Kneller's of those of the Court of Anne; besides a vast number of eminent Englishmen down almost to the present day, and many eminent foreigners connected more or less closely with English history or literature, as Francis I., Frederick the Great, Erasmus, &c. In looking over these portraits it is impossible not to wish that some of them—such, for instance, as the fine portrait of Newton—could be transferred to the National Portrait Gallery (and the removal of the Admirals to Greenwich is an excellent precedent); but whether that be possible or not, it would be comparatively easy to sweep out anything that is irrelevant from the spacious Queen's Gallery, and by adding to the many old portraits it already contains such as were suitable from the other apartments, and arranging them all in strict chronological sequence, to make it what it would then at once become, the finest English historical portrait gallery in existence, and one which in its way would not be likely to be superseded.

Naval Gallery, Greenwich Hospital.—Mainly, if not wholly, through the exertions of the late Mr. Edward Hawke Locker, the son of a distinguished admiral—himself a man of high taste and of singular energy in every good work—this gallery of portraits of distinguished naval commanders, and pictures of naval actions, was founded in 1823, in the most suitable of all localities, the Painted Hall, Greenwich Hospital, of which noble institution Mr. Locker was a commissioner. George IV., to whom the scheme was submitted, gave it "his cordial approval," and what was still better, transferred to Greenwich Hospital the extensive collection of portraits of the principal admirals of the reigns of Charles II. and William III. at Windsor Castle and Hampton Court. He subsequently added several pictures from his private collections, including Turner's grand 'Battle of Trafalgar.' The royal example found liberal imitators; and the collection is now a large and very interesting one. In looking at the pictures, it should be borne in mind that every picture has been presented to the Institution, the Commissioners regarding the funds of the Hospital as "exclusively devoted to the maintenance of the establishment." Beginning with portraits of Willoughby, Nottingham, Raleigh, Hawkins, Drake, and Cavendish, and with a representation of the 'Defeat of the Spanish Armada,' we have in chronological order almost all our bravest admirals, and many of our most famous sea-fights. A small ante-room is called the Nelson room from its containing portraits of Nelson, and several of his brother admirals, and a series of representations of leading events in his career. In such a gallery it is not artistic excellence we look for, and, while there are many excellent pictures here, some of the paintings are very far indeed from claiming to rank as works of fine art. But the visitor must have a strangely-constituted mind who can stand in this noble Hall and gaze around without receiving impressions deeper and more vivid than any produced by the most beautiful pictures when merely regarded as works of art.

The Dulwich Gallery, or Bourgeois collection of Paintings, is not a national gallery; but being open to the public on the same footing as the South Kensington galleries, and having a special character as a gallery of pictures, it seems fairly entitled to mention here. The collection was formed by Noel Desenfans, an eminent picture-dealer, by whom it was bequeathed to his friend Sir Francis Bourgeois, a painter of some note in his day, though of but slender ability as an artist. [BOURGEOIS, SIR FRANCIS, in BIOG. DIV.] Sir Francis dying in 1811, bequeathed the collection to Dulwich College; together with the sum of 2000*l.* and the reversion of other property for the purpose of erecting a gallery to contain the pictures, and a mausoleum for himself and Mr. and Mrs. Desenfans. The gallery in which the pictures are contained, and the adjoining mausoleum, were built accordingly from the designs of Sir John Soane. The gallery is a suite of five long but narrow rooms, sufficiently spacious perhaps for the pictures, which are for the most part of small size, but very insufficiently lighted. The collection itself comprises 355 pictures; some few of the paintings are by Italian, Spanish, and English artists, but the special interest of the collection arises from its consisting chiefly of Dutch and Flemish pictures of cabinet size—a class of works in which the National Gallery is very deficient. Most of the more eminent painters of the Netherlands are represented here, and of many there are very fine examples; but many of the pictures have small claim to the names they bear, and altogether the collection cannot be ranked among those of the highest order.

NATIONS, LAW OF. [LAW.]

NATRON. *Trona.* A commercial name formerly used to designate a native sesquicarbonate of soda obtained from Egypt.

NATURAL, a musical character, thus formed—

the use of which is, to make a sharpened note a semitone lower, and a flattened note a semitone higher; or, in other words, it brings into the scale of the natural key of C any note which had been made sharp or flat. But it must be observed, that the power of this character does not extend beyond the bar on which it appears, except where a lasting change of key is intended, in which case each natural placed at the clef removes a corresponding sharp or flat permanently, or until such sharp or flat shall be restored in like manner.

NATURAL PHILOSOPHY. [PHYSICS.]

NATURALISATION, from the Latin *Naturalis*, natural. "If an alien be naturalised," says Coke (Co. Lit., 129, a), "he shall be to all intents as a natural subject, and shall inherit as if he had been born within the king's allegiance." [ALLEGIANCE.] This rule, however, is subject to some limitations. [ALIEN.]

Formerly there could be no naturalisation except by Act of Parliament; but a simple and inexpensive method of obtaining similar advantages to those possessed by naturalised subjects has been provided by the statute 7 & 8 Vict. c. 66. This Act enables any alien who has come to reside in the United Kingdom with a view of settling, to present a memorial to the secretary of state, containing a statement of his age, profession, trade, or other occupation; the length of time he has resided in this country, and the ground on which he seeks to obtain any of the rights of a British subject; and praying for a certificate, which must be granted before further steps can be taken. The certificate granted by the secretary of state recites such parts of the memorial as, after due investigation, are found to be true and material, and professes to confer upon the applicant the rights and privileges of a British subject, except the capacity of being a member of the Privy Council, or a member of the Houses of Parliament, and except the rights and capacities (if any) specially excepted in and by such certificate. This document must be enrolled in the Court of Chancery, and within sixty days after its date the memorialist must take and subscribe an oath of allegiance. It is considered to confer on the alien a temporary character only as a subject; that is, the alien cannot, on returning to his own country, there claim the protection of the British flag as if he were a natural-born subject. The course of proceeding to be adopted by aliens wishing to become naturalised is left, so far as details are concerned, to the Secretary of State, and the fees are fixed by the Lords of the Treasury.

The number of foreigners naturalised previous to the passing of 7 & 8 Vict. c. 66, did not on an average exceed seven or eight a-year, and the number who applied for letters of denization did not exceed twenty-five annually. It may be added, that that statute naturalises *de facto* any alien woman who marries a British subject, in consequence of which, the notorious Mrs. Manning, when indicted with her husband for murder, was held not entitled to a jury *de medietate lingue*.

NATURE, LAW OF. [LAW.]

NAUMACHIA, the representation of a sea-fight among the Romans, which was sometimes performed in the Circus Maximus or amphitheatre, water being introduced sufficient to float ships, but more frequently in places made especially for the purpose, which were called Naumachiae. Julius Caesar appears to have been the first who gave a representation of a sea-fight on an extensive scale. He dug a lake in the Campus Martius for the purpose, which however was filled up in his lifetime (Dion Cass., xl. 23; Suet., 'Jul.', c. 39, with Casaubon's note, and c. 43). Augustus also dug a lake near the Tiber for the same purpose, which was afterwards turned into a park or plantation ('*nemus*;' Suet., 'Oct.', 43; Tacit., 'Ann.', xii. 56). Another lake was dug in the Campus Martius by Caligula (Dion Cass., lix. 10); but Claudius exhibited a naumachia on the lake Fucinus, now Celano. (Suet., 'Claud.', 21; Dion, lx. 33; Tac., 'Ann.', xii. 56.) The old naumachia (*vetus naumachia*), in which Titus is said by Suetonius ('*Tit.*', 7) to have exhibited a sea-fight, has occasioned some dispute among the learned; some understanding it to be the Circus Maximus, and others the lake dug by order of Augustus (Ernesti on Suet. '*Tib.*', 72). Domitian appears to have been the first who erected a building of stone around these artificial lakes (Suet., 'Dom.', 4, 5). Previous to his time the spectators appear to have sat upon wooden benches, which might be easily made to rise gradually above one another with the earth which had been dug out of the artificial lake. In later times the naumachiae were usually surrounded with buildings like the amphitheatre or circus.

The ships which were engaged in these sea-fights were divided into two parties, which were called respectively by the names of different maritime nations, as the Tyrian and Egyptian fleets (Suet., 'Jul.', 39), the Sicilian and Rhodian (Suet., 'Claud.', 21), &c. The combatants, who were called Naumachiarii (Suet., 'Claud.', 21), were usually captives or criminals, who fought to death, unless saved by the clemency of the emperor. These sea-fights are said to have been exhibited on such a scale of magnificence and splendour as almost to surpass our belief. In the naumachia exhibited by Nero there were sea-monsters swimming about in the artificial lake (Suet., 'Nero', 12), and Claudius

caused a Triton, made of silver, to be placed in the middle of the lake Fucinus, who was made, by machinery, to give the signal for attack with a trumpet. (Suet., 'Claud.', 21.) In Domitian's naumachia the number of ships engaged was almost equal to two real fleets (*pæne justæ classes*, Suet., 'Dom.', 4); and in the sea-fight on the lake Fucinus, there are said to have been no fewer than a hundred ships, and 19,000 combatants. (Tac., 'Ann.', xii. 56.)

NAVAL ARCHITECTURE. [SHIP.]

NAVE. [CHURCH.]

NAVIGATION. The history of the compass is the history of the rise and progress of navigation. Under that head (COMPASS) we have already shown the developments which in course of time enabled the mariner to abandon the tediousness of a coasting voyage, when desirous of reaching a distant port, and to avail himself boldly of such aids as the resources of the period afforded for ascertaining his position by celestial observation and the use of charts.

Certain it is that navigation was practised as an art, by the sailors of the East, previous to the voyage of Vasco de Gama round the Cape of Good Hope, during the 15th century.

The publication of Napier's tables of logarithms, in 1614, may fairly be considered as the origin of the present system by which ships are navigated to distant parts, although at that period and long afterwards, the want of better instruments was a great detriment to the seaman whose facilities for computation far exceeded in amount those for observing the celestial bodies:—for although Hadley's quadrant was described in the '*Philosophical Transactions*,' so early as 1731, some years elapsed before its use became general among those who from habit had been content with the cross-staff or the fore-staff. Indeed it was not until the close of the last century that the cross-staff fell into disuse.

It is somewhat singular that this order of things has been reversed in so pre-eminently maritime a country as Great Britain; for at the present time the perfection of instruments has contributed more especially towards increased accuracy by observation, while it is to be regretted that computation has been allowed to retrograde.

Before entering upon any details as to the art itself, it will be well to glance at those who are called upon to practise navigation. Under the heading GREAT CIRCLE, or TANGENT SAILING, we have already adverted to certain unsatisfactory circumstances connected with the present state of nautical education as affecting the real question and interests of navigation. Possessing the finest merchant service in the world we are absolutely deficient in that essential educational groundwork, which can alone constitute in any individual the complete navigator. The Board of Trade perceiving the insufficiency of the general education of those who, necessarily leave school at an early age to join the sea service, wisely instituted a system of examination for sea officers, and the merchant has already learnt to appreciate increasing competency in ship-masters who, stimulated by the desire of honourable public mention, have obtained *extra* certificates. But it is to be lamented that deeply rooted impediments exist in the path of progress which it would be well to remove. These are never so apparent as when we attempt to compare the English system of education with any foreign one. If we seek a standard for comparison we have it in the corresponding classes of men who occupy the same relative maritime position as those of our own country.

To say that navigation is the art of moving a ship from one part of the ocean to another, is the usual prefatory definition; but so various are the methods by which such changes are effected that these are, as a whole, justly considered as an art. For instance;—it is easy to convey a vessel from a port or place to a not far distant headland, or along a coast several points of which lie within sight of the usual track of the vessel. To do this is the mere work of a sailor or one accustomed to the management of the masts and sails, &c., so as to be able to steer in the right direction. Of such nature was the work of our earliest navigators, before the compass came into general use. But even in these short passages it will sometimes occur that heavy gales drive the mariner beyond the limits of his knowledge of the locality as depending upon sight of land, and throw him upon some extra resources, such as he can obtain by loose speculations founded on the appearance of the heavenly bodies, or by the use of the lead-line. A very large portion of master mariners are of this class; they plod their way about our coasts, ignorant of any scientific means whatever of navigation. Others, again, traverse the English Channel, the Irish Sea, the North Sea, &c., and have so far consulted *system* as to have acquired the rough knowledge of a quadrant and the method of taking by it a meridian altitude for the latitude: with this, and the occasional use of the lead-line, together with some such slight initiation into plane sailing as can be gathered from an ordinary epitome, this very large class of navigators perform their voyages not only with celerity but certainly with marvellous safety and regularity. Simple, however, as the nautical operations of these may appear to the mere landsman, a vast amount of valuable local knowledge is treasured in their memories. Nor is this local knowledge to be mistaken for the mere ability to recognise points of land, or glimpses of the coast or lighthouses, &c.; but it is the deep study of the ocean bed which constitutes mainly the highest attainment of the so called over-sea pilot. This together with an acquaintance with the peculiarity of the tides, so variable in their courses along the coast line, and a knowledge of their periodical ebb-

ings and flowings over or about various dangers, constitutes the study of a lifetime; so that we, when speaking of the oldest pilot, seem to imply the ablest pilot—as the ability referred to is attainable only by long observation and experience. Some masters of coasting vessels are of a still higher grade as regards education, inasmuch as when the vessels they navigate are of the burden of 100 tons, not only must the master himself have received a certificate of examination by officers of the Board of Trade, but one other officer, at least, in the vessel must be also certificated. Perhaps no other nation possesses so large a number of these daring and devoted seamen; trained in all weathers and in all seasons, they acquire a position among unpretending navigators, which would render comparison of them with those of other nations a source of pride and congratulation.

It is remarkable, that while miners and manufacturers have their special schools, surgeons their colleges, men of law their inns of court; the clergy, their universities; the over-sea-officers, or ocean navigators, a body of men who form a large majority of the ship-masters of England, have no suitable schools of navigation. Teachers are not wanted, it is true, but it is what they teach, or rather what they *do not teach* that specially needs public attention. In all other branches of science, a knowledge of the *why* and the *wherefore* is deemed indispensable to the proficiency of the student, but in navigation alone, a person is absolutely doomed to work blindfold, as regards the very ground-work on which all practical navigation rests. For not only do the very best works in use set at nought the necessity for a proper foundation being laid in the doctrine of spherics, and projection in particular, but in the highest examination of a captain by the Board of Trade for an extra certificate, it is required only that he be able to explain enough of spherics to illustrate the nature of great circle sailing: he is “*not required to go into the calculations.*” It is no reproach to our rulers that such is the case. Evils so extensive have not been the growth of recent years. Remedies are yet required. The establishment of institutions of a higher order for instruction would tend to remove such evils, and would inevitably promote the production of works of a superior character.

In navigation we have to deal with changes of a ship's position as sailing upon a spherical figure. It may be said, that the formulæ used in Mercator's, or middle latitude sailing, are sufficiently simple for general practice; yet how few in the merchant service can even construct the figure. And again in great circle sailing, who would not prefer seeing a merchant captain, when desirous of finding his tangent course, use an elegant, short, but exceedingly simple method by construction, which he *would* understand, to the more tedious method of calculation which he *would not* understand. Of far more importance is it to the nautical astronomer, who alone deserves the name of navigator, to clearly comprehend the nature of spherical trigonometry. All his problems and daily observations are the practice of spheric operations. The imaginary lines of the “*vast concave*” are designated and estimated by terms derived from the doctrinal attributes of the sphere. If then we inquire how an ordinary so-called navigator makes use of celestial observations while totally ignorant of principles, we are constrained to a confession, which, were not the ship-masters themselves loudly complaining of its truth, would stigmatise our mercantile marine, while the onus of the defect actually rests, not with them, but with the votaries of science themselves. How can it be, that while 200 years since every work on navigation taught spherics both by projection and calculation, in 1860 not a work in this great country gives the same facilities for a seaman's use?

The cause of this may be thus traced. Towards the close of the last century, various elegant diagrams for the aiding of the mariner by saving the labour of calculations were published in England. As an example, the perhaps most elaborate and in themselves most ingenious of them were by Margett in about 1772. A means of working, which was totally independent of calculation, soon began to be found a convenience to sea officers. Those of the greatest school of navigation ever formed, namely, the officers of the late East India company possessed such pleasant and interesting aids as Margett's ‘*Tables of Longitude*,’ and more recently, sets of ‘*Linear Tables*,’ &c. &c.; these gradually superseded calculation by logarithms in operations derived *directly* from the doctrines of the sphere. [SPHEROGRAPH.] And again, ingenious formulæ sprung from various equational combinations, hiding from the mind's eye their palpable origin, until now, the sailor unfortunately has nothing else to rely on. These formulæ are, still more unfortunately, considered useful in proportion as they become condensed and shorter. We have thus blindly and unconsciously offered a premium to mathematicians for the obscuration of those principles of which a proper knowledge is now claimed on behalf of navigators. The abridgment of formulæ in itself is not to be stigmatised; it was, however, in the circumstance of such abridgments occurring just at a period when diagrams entered largely into the practice of the day, in which lay their danger. Nor do we complain of diagrams, merely as such, but the great evil has been the publication of such as illustrate no system, or assist in no elementary study. If they had helped in the demonstration of spheric principles, calculation itself would have been simplified and retained in practice. A very long experience in educational matters enables the writer (who for upwards of thirty years has anxiously watched the question, being himself a navigator), to assert that all nautical diagrams which are not

palpably deduced from the projections of the sphere, namely, such as the stereographic, orthographic, and gnomonic, have a baneful tendency; while on the contrary, such diagrams as are really illustrations of, and demonstrative of, spherics, cannot be too plentiful. It follows then, that the present generation of navigators want assistance in spherics. It may be suggested that to attempt a sudden remedy would be impolitic. The authorities might, however, as a first step insist in their examination of an ocean captain, to see that he knew enough of stereographic projection to enable him to answer ordinary questions by spheric construction. But everything that can be done to illustrate stereographic projection is worthy the encouragement of the Board of Trade. Navigation therefore, as a branch of highly important practical science, does not at present in England take its legitimate place. Young sea officers require a peculiar education. The Board of Admiralty have taken the initiative, and in H.M. Navy, the privations which affect the merchant service do not exist. It is a notorious fact, that whereas in other professions, experience increases knowledge of principles; in navigation the older practitioner knows less of them than the young sailor fresh from his examination.

As regards the nature of the operations used in conducting a ship's course at sea, we give details under various heads, such as COMPASS; DEPARTURE; GREAT CIRCLE OR TANGENT SAILING; LATITUDE AND LONGITUDE; LEAD-LINE; LOCAL ATTRACTION; LOG AND LOG-LINE; LOG-BOARD AND BOOK; SAILING, &c.; to which we refer.

NAVIGATION LAWS. [SHIP AND SHIPPING.]

NAVY. A few leading facts as to the rise and progress of the British navy will form a fitting introduction to the main subject—its present constitution and force.

In the early part of the Christian era, so rude was the build of vessels, and so inadequate were they to contend with the winds and waves, that it was not until the reign of the emperor Probus, A.D. 276–82, that the veil of terror hanging over the ocean and distant voyages was removed. That emperor, in pursuance of his plan of colonising the border lands, which were exhausted by war, with people from the crowded countries of the barbarians, had carried a party of Franks into Pontus, with a view of defending that country against the Alani. Love of home induced some of these people to attempt their return; they seized ships on the Euxine, and plundered the coasts of Greece, Asia, and Sicily, either to supply their wants or for revenge: passing the pillars of Hercules, they veered to the right, and completed their voyage by disembarking at the mouth of the Rhine. From this voyage we may date the origin of nautical enterprise. The Saxons took advantage of the rich harvest thus opened to all who would attack the Roman provinces by sea, and ravaged the coasts to such an extent as to oblige the Romans to establish a fleet in the English Channel to repel them. After the Saxons had been long in possession of England, they lost their naval arts, and in their turn became a prey to the constant attacks of the Sea-kings, Vikingr, and other pirates. We have no record of the size or number of the vessels which sustained so many conflicts with the Danes in the 9th century. Alfred the Great was the founder of the English navy. He first perceived the necessity of a fleet to protect the coast from the swarms of pirates in the northern seas. A slight advantage gained by some ships of his over the Danes, in 876, induced him to build long ships and galleys, which, as his countrymen were not competent to manage them, he manned with such piratical foreigners as he could engage. After he had driven out the Danes, he applied his talents to improve his ships, and built vessels higher, longer, and swifter than before, some rowing thirty pairs of oars, others more. Ethelred made a law that whoever was lord of 310 hydes of land should furnish and build one vessel for the service of the country.

William the Conqueror established the Cinque Ports, and gave them certain privileges on condition of their furnishing 52 ships for 15 days, in case of emergency. King John claimed for England the sovereignty of the seas, and declared that all ships belonging to foreign nations, which should refuse to strike to the British flag, should be deemed fair and lawful prize. In the year 1293, an English sailor having been killed in a French port, war ensued, which it was agreed to settle by a naval action, which was fought in the middle of the Channel, and the English, being victorious, carried off above 250 sail. In 1340, when King Edward III. with 240 ships was on his voyage to Flanders, he fell in with and completely defeated, off Sluys, the French fleet of 400 sail, manned with 40,000 men. The same monarch blockaded Brest with 730 sail, containing 15,000 men. Many of the ships composing these fleets were Genoese and Venetian mercenaries, but they must have been very small, and the numbers of ships and men are probably exaggerated. Henry V. had something of a navy, for we find among the records in the Tower, a grant under his hand of annuities to “*the maistres of certaine of our owne grete shippes, carrakes, barges, and ballyngers.*” Henry VII., who succeeded in 1485, seems to have been the first king who thought of providing a naval force which might be at all times ready for the service of the state. He built the Great Harry, properly speaking the first ship of the royal navy; she cost 15,000*l.*, and was accidentally burnt in 1553. Henry VIII. perfected the designs of his father. He constituted the Admiralty and Navy Office, established the Trinity House, and the dockyards of Deptford, Woolwich, and Portsmouth; appointed regular salaries for the admirals, captains, and sailors; and made the sea service a distinct profession:

he also made laws for the planting and preservation of timber. In 1412, when a fleet was fitted out against France, under Sir Edward Howard, lord-high-admiral, the following allowances were made:—

	s.	d.
For his own diet, maintenance, wages, and rewards, per diem	10	0
Each captain for ditto, ditto	1	6
Every soldier, mariner, and gunner, for his wages per lunar month	5	0
And for his victuals	5	0

The ships of this period were high, unwieldy, and narrow; their guns were close to the water, and they had lofty poops and prows, like Chinese junks, insomuch that Sir Walter Raleigh informs us "that the Mary Rose, a goodly ship of the largest size, by a little sway of the ship in casting about, her ports being within 16 inches of the water, was overset and sunk." This took place at Spithead in the presence of the king, and most of her officers and crew were drowned. The Henri Grace de Dieu, the largest ship built in this reign, is said to have measured above 1000 tons. At the death of Henry VIII., the tonnage of the navy was 12,000 tons. Elizabeth increased the navy greatly. The fleet which met the Spanish Armada numbered 176 ships, manned by 14,996 men; but these were not all "shippes royal," for she encouraged the merchants to build large ships, which on occasion were converted into ships of war, and rated at 50 to 100 tons more than they measured. She raised the wages of seamen to 10s. per month. Signals were first used in this reign as a means of communication between ships. In 1603 the navy had 42 ships, measuring 17,000 tons. In the reign of James I. lived the first able and scientific naval architect, Phineas Pett, and the king had the good sense to encourage him. Pett introduced a better system of building, and relieved the ships of much of their top hamper. Before the civil wars broke out, Charles I. built the Sovereign of the Seas, of 100 guns, and measuring 1637 tons. In this reign the navy was first divided into rates and classes. Cromwell found the navy much reduced, but his energy restored it, and he left 154 sail, measuring 57,643 tons, of which one-third were two-deckers. Cromwell first laid before parliament estimates for the support of the navy, and obtained 400,000*l.* per annum for that purpose. The navy flourished under Charles II., with the Duke of York at its head, assisted by Samuel Pepys, as secretary, until 1673, when the duke's inability to take the test oath caused his retirement, and the king's pecuniary difficulties leading him to neglect the navy, it fell into decay. The Duke of York was recalled to his post in 1684, and at his accession in the following year there were 179 vessels, measuring 103,558 tons. James II., on coming to the throne, took active measures for the restoration of the navy; he suspended the Navy Board, and appointed a new commission, with which he joined Sir Anthony Deane, the best naval architect of the time, who essentially improved the ships of the line by copying from a French model. Four hundred thousand pounds per annum were set apart for naval purposes, and so diligent were the commissioners that at the Revolution the fleet was in excellent condition, with sea stores complete for eight months for each ship. The force was 154 vessels, carrying 6930 guns, and 42,000 men. Of these vessels nine were first-rates.

William III. immediately on being placed on the throne went to war with France, whose navy was then very powerful; in 1681 it consisted of 179 vessels of all sorts, carrying 7080 guns, besides 30 galleys. An Act was passed in his second year, for building 30 ships, to carry 60, 70, and 80 guns respectively. The dockyard at Hamoaze, out of which has since grown the considerable town of Devonport, which now returns two members to parliament, was then established. Queen Anne found at her accession the navy to consist of 272 vessels, measuring 159,020 tons, but this estimate includes hulks, hoys, and other vessels not carrying guns. At the death of Anne in 1714, the number of ships was less, but the tonnage increased, being ships 198, guns 10,600, tons 156,640. The parliamentary vote of that year was 245,700*l.*, and 10,000 seamen and marines. During the first four years of George I., large sums were voted for the extraordinary repairs which were required after the long war. A new establishment of guns also was ordered in this reign. The navy remained stationary till 1739, when hostilities commenced against Spain, and the navy was augmented, particularly in the smaller classes of vessels, and the dimensions of several classes were enlarged. War broke out with France in 1744, at which period there were 128 sail of the line. At this time all prizes taken by H.M.'s ships were declared to be the property of the captors. In 1747 a naval uniform was first established. The navy increased vastly during this war, in which 35 sail of the line were taken or destroyed by the English. George III. at his accession found the navy to consist of—

Ships of the line	127	} measuring 321,104 tons.
" 50 guns and under	198	

The vote for the year 1760 was 432,629*l.*, and 70,000 seamen and marines. In the short war of 1762, 20 sail of the line were added to the navy, and at the end of the American revolutionary war it was composed as follows:—

Sail of the line	174	} about 500,000 tons.
Under	203	

The navy was kept in a high state of preparation, and when, on the 1st of February, 1793, the French republic declared war against England, this country was not unprepared. A period now commences in which the gigantic efforts made by England, and the protection necessary for a mercantile marine, which almost monopolised the commerce of the world, raised the British navy to such a height as to enable it single-handed to maintain the sovereignty of the seas against all other navies combined. Sir Charles Middleton, afterwards Lord Barham, had, when comptroller of the navy in 1783, established the regulation that a great proportion of stores, sails, &c., should be laid by for each ship in ordinary; so that in a few weeks after the declaration of war there were 54 sail of the line and 146 smaller vessels at sea. The vote for the service of the navy was 5,525,331*l.*, 85,000 seamen and marines. The navy of France had never been so powerful: it amounted to above 200 vessels, of which 82 were of the line, and 71 in addition were immediately ordered to be built. The English had about 115 sail of the line fit for service, but the majority of the French ships were larger and finer, and carried heavier guns on their lower or principal battery. The following abstract will show the losses on both sides up to the peace of Amiens, exclusive of the casual losses:—

	Captured.	Destroyed.
British ships of the line	5	0
" smaller vessels	37	9
Total	42	9
French ships of the line	32	11
Dutch " "	18	0
Spanish " "	6	5
Danish " "	2	0
Total	58	16
French smaller vessels	266	44
Dutch " "	62	6
Spanish " "	57	10
Total	443	76

This estimate does not include 807 privateers, chiefly French, taken and destroyed. Of the above, 50 sail of the line and 94 under that size, were added to the British navy.

During the peace of Amiens preparations for war were actively continued on both sides, and the declaration on the part of England was made in the month of May, 1803, at which time the navy was of the following force, as compared with 1793:—

	Ships of line.	Under.	Tons.
1793	153	411	402,555
1803	189	781	650,976

Notwithstanding the apparent increase, there were not so many line-of-battle ships fit for sea at the latter as at the former period by about ten. The French force in serviceable line-of-battle ships in March, 1803, was 66, the British 111. During this war there were employed from 100,000 to 120,000 seamen and marines till 1810, when the number was increased to 145,000. There were about 100 sail of the line, 150 frigates, and above 200 sloops, besides small armed vessels, amounting in the whole to about 500 sail of pendants constantly employed. The following abstract shows the losses on each side during the war:—

	Captured.	Destroyed.
British—Ships of the line	0	0
Under	83	7
	83	7
Enemies'—Ships of the line	55	14
Under	79	23
	134	37

of which 33 sail of the line and 68 under were added to the British navy.

In George III.'s reign the dockyard of Pembroke was established.

The parliamentary vote for the service of the navy, 1839–40, was as follows:—

Officers	3,400	For the effective service	£3,492,132
Petty officers	3,998	For the non-effective service	1,488,221
Seamen	12,846	Other departments, namely, convicts and transport of troops	217,158
Marines	20,244		
	9,000		
	29,244	Total charge	£5,197,511

The following tables will show the force of the British navy at three distinct periods, namely, the breaking out of the French revolutionary

war; a few years subsequent to the peace; and in 1839: also the nava force of other countries possessing a navy, in 1839:—

RATE.	1793.				1820.				1839.			
	In Commis.	In Ordinary.	Building.	Total.	In Commis.	In Ordinary.	Building.	Total.	In Commis.	In Ordinary.	Building.	Total.
First . . .	1	2	2	5	2	14	7	23	4	14	6	24

Grand total . .	135	166	20	321	113	244	108	465	175	149	68	392

Until the Restoration there does not appear to have been any precise division into classes, nor have we any account of the armament of ships. At that time certain ships were ordered to be built to carry the following:—

Description of Guns.	1st Rate. 780 men.	2nd Rate. 660 men.	3rd Rate. 470 men.
Cannon = 42-pounders . . .	26	—	—
Demicannon = 32-pounders . .	—	26	26
Culverins = 18-pounders . . .	28	26	—
Demiculverins = 12-pounders . .	—	—	26
Sakers = 6-pounders . . .	28	26	—
Forecastle . . .	4	—	4
Quarter-deck . . .	12	10	10
3-pounders . . .	2	2	4
Total number of guns . . .	100	90	70

There was, however, no uniformity preserved; and in 1745 a committee was appointed, which recommended certain changes in the rating and arming, which however were not adhered to any more than the former systems. At the peace the Board of Admiralty represented this to the Prince Regent in a memorial, and a system was adopted; but the introduction of ships of much larger tonnage and wholly different armament has rendered the classification obsolete. The classification now in use is as follows:—

1. *First Rates*, to comprise all ships carrying 110 guns and upwards, or the complements of which consist of 1000 men or more.

Ships of the Line.	FRANCE.				RUSSIA.				AMERICA, U.S.				EGYPT.				TURKEY.				HOLLAND.				DENMARK.				SWEDEN.				SPAIN.				NAPLES.				SARDINIA.

Holland had 104 gun-boats; Denmark, 67; Sweden, 337.

Second Rates, to comprise one of her Majesty's yachts, and all ships carrying under 110 guns and more than 80 guns, or the complements of which are under 1000 and not less than 800 men.

Third Rates, to comprise her Majesty's other yachts, and all such vessels as may bear the flag or pendant of any admiral superintendent or captain superintendent of one of her Majesty's dock-yards; and all ships carrying 80 and not less than 60 guns, or the complements of which are under 800 and more than 600 men.

Fourth Rates, to comprise all frigate-built ships of which the complements are 600 and not less than 410 men.

Fifth Rates, to comprise all ships the complements of which are 400 and not less than 300 men.

Sixth Rates, to consist of all other ships bearing a captain.

2. Sloops:

To comprise all vessels commanded by commanders.

3. All other ships commanded by lieutenants, and having complements of not less than 60 men.

Smaller vessels, not classed as above, to have such smaller complements as the Lords Commissioners of the Admiralty may from time to time direct.

In 1839 it will be seen that England was in reality no longer able to meet a sudden emergency. The public voice aided the discernment and energy of Government, and a change was resolved on. Prosperity had proved a dangerous narcotic. The question of war or peace had been considered as one of mere national income and expenditure, rather than one of vital importance, as involving our defence and safety. A prevalent feeling that a pressing necessity had arisen led the Government to arm and man a few ships, until they grew into a Channel squadron; and Spithead once more showed to a new generation some results of naval preparation. Then for a time the rulers of England were, from public encouragement, more free to enter upon a wider course, which soon told upon the resources pre-eminently possessed by this country. New requirements of science resulted in immense changes in the form, mode of arming, and propulsion of ships-of-war.

At this period the Vernon frigate was stated in triumph to be larger

than a first-rate of the year 1745; the said Vernon being of the measurement of 2080 tons. But so great has been the advance of naval architecture as a science, as compared with preceding years, that in 1860 we find the said Vernon, of 51 guns, lying in the Medway, a mere pigmy in comparison with other frigates, one of which, the Galatea, of 26 guns, is of the burden of 3202 tons.

It is really difficult in a subject of such vast range as that of our navy to select judiciously, or to reject advisedly, details conducive to our purpose. During the last fifteen years the question of naval strength has been growing into huge dimensions, as nourished by the stirring activity of our rulers, consequent upon the immense changes which various causes have produced. Among these causes steam has so deeply influenced all naval matters, that the navy of 1860 cannot easily be compared with that of any previous period; nor is it easy to convey an accurate notion of the extent of such changes within the proper limits of an article in a Cyclopædia. The very lines of demarcation between long familiar terms have been absorbed and obliterated. As an instance, the words corvette, or frigate, or sloop, or brig, &c., give now no positive idea of the powers of ships described by these terms. The lines of construction, the proportions of the extremities, the description of armament, as consisting of solid or hollow shot, or as round or cylindrical, pointed, curved, or truncated,—investigation of all these matters in naval warfare, tending towards greater weight of metal in guns, in order to facilitate longer ranges in projectiles, such ranges still further depending for accuracy upon the peculiar shape of the gun-chamber or bore, whether as circular or hexagonal, &c., or as grooved or rifled,—all these, we say, throw upon the naval architect a demand for change in the forms of vessels, and a mass of considerations, of which his predecessors had little or no experience.

To enter upon the various stages of improvement induced by individual talent would be foreign to our object: it is enough to remark that the names of Seppings, Hayes, Symonds, and others, and especially of the distinguished officer Sir B. W. Walker, late the surveyor of the navy, but who now fills the newly created office of comptroller of the navy, will be remembered with respect by posterity, as having each in his own method promoted, with national advantage, the subject of ship-building for warlike purposes to its

* In 1793 the fourth-rates on two decks formed part of the line of battle.

present state. The extreme difficulties encountered by the latter during an extraordinary period of total revision of the navy, lay in the required alteration of ships which had been partly or totally built; the cutting of others to lengthen for the reception of screw-engines; the various perplexing circumstances consequent upon failures or even unexpected successes in the scientific experiments of all maritime nations, required the energies and watchfulness of not merely the man of science, but the ready tact and penetration of the accomplished sailor and experienced and observant sea-officer. The exertions of the directing head have been worthy the honours decreed by the nation: while the apparently splendid line-of-battle ships of a neighbouring nation, can scarcely fight their lower-deck guns in rough weather, the British nation now possesses in her royal navy the finest sea boats and floating batteries in the world.

We dwell thus upon the importance of these considerations because, when the paddle-ship was first thought likely to supplant altogether the sailing-ship, there arose a sense of uneasiness and doubt of our safety in the minds of those who were most intimate with the progress of affairs, from the consideration that the strength of the old fleet lay in its "broad-sides," which, however, the introduction of the paddle nearly paralysed. Hence it became necessary to increase the calibre of the reduced number of guns which a paddle-ship could accommodate. But this, again, demanded total readjustment of the framework of the ship; so that some, to be rendered effective as men-of-war, needed alteration at one end, some at the other, to insure a proper amount of buoyancy in compensation for novelties in the new distribution of weight of metal, &c.

The question of naval architecture for warlike purposes was one of special anxiety in and about 1844. The continental threatenings of the year 1839 had deeply impressed the country with a conviction of insecurity, and the exertions of neighbouring nations stimulated an unusual activity in our arsenals. In that year the sailing properties of certain forms of hull were tested in the construction of five brigs, as 12-gun brigs, intended to compete with three of the 10-gun brigs of the old model, namely, the Pantaloon, Waterwitch, and the old Cruiser.

The new ones were as under, namely:—

Flying Fish	built by Sir W. Symonds.
Osprey . . .	Blake.
Espiegle . . .	Chatfield.
Mutine . . .	the School of Naval Architecture.
Daring . . .	White, of Cowes.

Only two other vessels of the gun-brig class were afterwards built, these were the *Mariner* and the *Kingfisher*. From the above period we may date an era memorable in the records of the English navy. Various experiments then commenced became instrumental in forming a fleet, such as the country delighted to hail with acclamation, as it afterwards mustered at a grand naval review at Spithead in August, 1853. This was, however, but a splendid holiday display; nor could the many thousands who beheld that most imposing national spectacle have suspected that before another year a naval armament of England would be led by our Queen in person towards the Baltic, and that her naval supremacy was once more to be put to the test of battle in a war with Russia; but, of the many thousands who waved and cheered this gallant fleet from our shores, some will not forget the one deep sentiment of anxiety, when reminded, on reflection, that, from novelties of armament and propulsion, naval war was then (as it would be now) an *experiment*.

The fleet of 1854 differed from those of former wars. It was not composed of similar materials, either as regards men or ships. In 1854, not only were men wanted to man the fleet, but those who did enter as able seamen were unaccustomed to the very improvements which science had introduced. The work of an engineer in those days could only, in the minds of so peculiar and isolated a race of beings as British sailors, be viewed in the light of innovation. A new round of duties seemed, in 1854, to have descended upon him, or to loom before him. Instead of a splendid fleet of sailing-ships, with which he had, in its details, become acquainted, and whose evolutions, depending upon the smartness of the crews, used to be governed by one set of naval rules, under which his experience had been matured, the fleets of the Baltic and Black Sea were composed of three distinct and separately-managed classes of vessels; where, moreover, the sailing-ships, his former pride, took the lowest rank in point of efficiency, either in sailing or warfare.

In the Baltic fleet the screw squadron had 28 ships.

"	paddle	"	23	"
"	sailing	"	4	"

Total 55 ships.

In the Black Sea fleet the screw squadron had 10 ships.

"	paddle	"	18	"
"	sailing	"	12	"

Total 40 ships.

In 1855, there were in the British navy 107 paddle-steamers, and 78 screws.

Steam, then, had in 1854 established its claims to the attention of our naval administration as a powerful auxiliary at sea. A few paddle-steamers only had attended the Channel fleet of 1845. But, as that fleet passed outside the Nab Light, a long low corvette, of some 700 or 800 tons, was propelled by a force which showed the *Rattler* to have attained a speed exceeding that of all other vessels present. In her the screw had achieved a triumph; had taken unquestionable precedence over the paddle-wheel, and had established a means of propulsion that was soon to effect a mighty change in the naval forces of Great Britain. The apathy, real or otherwise, which might seem to have attached to the British naval executive through a long peace, and up to 1845, certainly from that year decreased. In 1845 alone, no less than 23 screw-steamers were added to the British fleet, and formed the nucleus of the enormous change to which our attention must be called before our dismissal of that branch of investigation which refers to what the naval force has been.

In 1845, as we thus notice, the *Rattler* was the forerunner of great changes in the mode of propulsion of our ships-of-war. The paddle-steamers had before that been but partially substituted for the sailing-ship. The exposure of a vessel's sides, and the machinery of the paddle, to the damaging effect of an enemy's shot; the position of her engines, even as questionably protected by her coal-bunkers; the probable destruction of her paddles early in an action; the nature of the crew, sufficient only for a mere steamer; the great diminution in the possible armament of a ship in which so much space was required for paddles, and the consequent interference with that which in naval fights had hitherto worked such destruction in our enemies' ships, namely, the broadside; together with the necessity for arming according to greatly altered lines in the construction of ships destined for steam navigation,—these were serious considerations for an Admiralty Board. They perplexed the question of the precise form of a ship to such an extent, that while the public were speculating on the general improvements which it was not difficult to foresee must spring from such a combination of novel circumstances, enough was on the hands of the executive to have paralysed a body less ably supported. The change from a sailing fleet to one of mechanical propulsion, whatever might be the particular mode in which such propulsion was to be effected, was one of those gigantic movements that had much more influence upon the security of the country than would appear to common observation. The anxiety and occasional fears of statesmen who felt the vital tendency of passing events, the driving of our best sailors from the service, the enormous sums necessary for experiments,—these, and other weighty considerations, increased the high responsibilities of the Board of Admiralty; and it would be unjust to estimate the value to the country of this or that board for the administration of naval affairs on account of failures or expenditure, or on account of delays, which were possibly the result of no want of energy at the time.

While England was thus investigating the question of naval armament, other countries were also vigorously presenting the whole matter to scrutiny and reform. There could be no question as to the recent inferiority of England as regards her defence by sea. Such then was the opportunity for rival nations to push forward their developments. Indeed, no sooner had the war with Russia terminated than all the resources of that country were given to the renewal of her ships, and the recovery of a fleet. Her emissaries were soon to be found in every sea-port in England, and no novelty in science which promised advantage in future warfare, or even in the fitting of ships, was neglected by Russian naval officers. It was no uncommon sight for Russian steamers, built as well in the Thames as elsewhere, to proceed to sea with fittings upon new principles,—so new, that the English ship-owners even had not yet been made acquainted with their existence. It is questionable whether we have any correct notion of the rapid strides thus made by Russia in rebuilding her navy, although certain lists of ships are before the world. The public occasionally had their attention drawn to the movements of other nations, and many disparaging comparisons have taunted our English executive; but, with all things in a state of change, such have been merely inducements in the Lords of the Admiralty to drive forward their experiments. But who can tell the probably enormous sums saved to the country by the cautious and, under circumstances without parallel in history, prudent hesitations which such changes seem now to have justified! The expenditure of vast capital would naturally, to a commercial people like the English, appear suspicious where positive and immediate benefit was not plainly discernible.

Whether the weakness which appeared to infest our sea-service, and the openly avowed discrepancies which were said to exist in the recent working of naval affairs, influenced a neighbouring nation, and, as on former occasions, cherished in her the hope of a future predominance, or not, certain it is that not only in the ships of the French navy, but in their arsenals, every preparation has been made for a desperate struggle on the ocean. The same difficulties which steam had introduced into our navy, must also have pervaded theirs; but it is significant that, notwithstanding the costly experiments made by this country, France should have recently possessed a fleet equal to, if not greater than our own, and one as perfect in all the scientific improvements of the period. Nor were the above the only serious causes of anxiety in the minds of the most experienced naval statesmen: for paddle ships

were of necessity restrained within certain limitations as to the size of their masts and the quantity of sail available, inasmuch as beyond a certain amount of canvas, it was found that a ship under sail could in a breeze actually *overrun* the paddle, which at such times became an incumbrance; and further, with diminished masts and rigging, the reduction in a sailor's work aloft threatened to deprive England of her so long boasted advantage over other nations in the superior skill of her seamen, thus, indeed, threatening to reduce her to the level of other powers; but the success of the *Rattler* demonstrated, in 1845, that while the dominant superiority of the screw-propeller restored space for the broadside armament, it did more,—it renewed, in the full rig of a screw steamer, necessity for that experience and dauntless activity and proficiency in seamanship aloft which has been so universally acknowledged and eulogised as an attribute of a British sailor. Happily, therefore, the screw line-of-battle ship, or the screw frigate of the present day, when under sail with her funnel reefed, presents no peculiarity of rig, except the neatness peculiar to an English man-of-war.

This also obviates another difficulty which long embarrassed the naval affairs of the country. With a paddle fleet, having reduced masts, and therefore less able to fully avail themselves of a favourable wind, the expense, though large, bore but little proportion to the many other inconveniences attending the necessary supply of coals to ships in commission; whereas in a screw fleet the assistance offered by the wind is always available, and much less coal is required, for after all the screw is but an auxiliary, to be used only in adverse winds or calms, except under emergency; while it fortunately admits of being used with sailing power, because it has been proved that a screw propeller can always be made to increase the speed of a ship under sail, and should accident happen to the machinery, the screw can be lifted, so as to give full benefit to the vessel as a sailer.

Perhaps the most important advantage over the paddle introduced by the screw is, that whereas the machinery of a paddle ship unavoidably exposes her main shaft and cranks and connecting rods to an enemy's shot, from their necessary elevation above the centre of gravity of the floating mass, the machinery for the screw and its main shaft admit of being placed below the water-line, and close to the keelson; while, again, the necessity for finer lines and greater length of hull in a screw ship produce an additional space, which generally suffices for the engine and fuel, without any decrease of stowage for provisions and stores.

The success of the *Rattler* encouraged the construction of a fine screw frigate, the *Arrogant*, launched in 1848, mounting 46 guns, and of the burden of 1872 tons. This ship may be said to be the pioneer of a new system, as regards frigates, for in 1852 was launched the *Imperieuse*, the first of a heavy class of frigates which are now the pride of the service. This fine ship is armed, like her successors, with 51 guns (50, and a pivot gun), and is of the burden of 2347 tons.

The year 1852 is also remarkable as being that in which the *Leopard*, the last (and it is supposed to be the *best*) of all our paddle steamers, was brought into the service: and also because in that year the first screw line-of-battle ship of two fighting decks was introduced, in the *Agamemnon*, the first of the 91's, being of 3074 tons, to correspond with which several of our three-deckers have since been cut down and similarly armed.

In the same year also the class of 21-gun corvettes, with one flush fighting deck, first made its appearance in the *Highflyer*, being of 1153 tons, and armed with 68's. The *Scylla* and others are of this class; but as war steamers the class will probably be allowed to wear out.

The superior speed of steamers, and the regularity with which voyages could be performed, threw upon the hands of the admiralty a large fleet of sailing-ships, the biggest of which in a calm would scarcely be a match for a screw-corvette of the present time. Although it must be borne in mind that the one important and only available test of the value of a steam fleet had been happily withheld; although the world has yet to learn the details and the horrors of an engagement between steam fleets; the judicious, though gradual increase in the number of screw-propellers used in the navy, seems in a measure to have cleared the political horizon of many threatenings and misgivings as to our continued superiority. The old English patriot again may breathe freely when he contemplates the apparently full-rigged line-of-battle ship, fitted with screw-propeller, and differing nothing in appearance from the old "walls" on which his youthful gaze dwelt with confidence and pride.

Enough for our purpose has been said of the general events which attach to the past of the naval force of Great Britain. We now consider its present condition, first presenting a condensed view of the forces of all the navies of the world, as compiled principally from Hans Busk's and other elaborate works on the subject, for the year 1859.

The naval force of Great Britain, according to the Navy List of July, 1860, is as follows:—

	Ships.
In the effective list we have of all sizes and arms . . .	572
Gun-boats, of which 59 are used as tenders, &c. . .	164
Ships and vessels in harbour service . . .	125
Cutters, &c., used as coast-guard tenders . . .	47
Total . . .	908

The total number of 908 ships does not include Admiralty lighters,

* Row-boats.

hoys, and various small craft employed in coasting and about the Royal Dockyards.

The number of seamen and marines voted for the navy in the session of 1860, was 84,100. In addition, a reserved volunteer force of seamen to the number of 30,000, was provided by the 22 & 23 Vict., cap. 40, passed in the session of 1859.

The engineers of the navy consist of 8 inspectors of machinery, of whom 5 are afloat; 139 chief engineers; 6 acting first-class in charge; 148 first-class assistants; 207 second-class; and 530 third-class.

All mere abstracts regarding maritime forces must be defective, unless the number of guns, weight of metal (distinguishing solid shot

from shells), the speed of ships, the stowage, the steering qualities, spread of canvas, &c., be taken into consideration. The preceding tables will, however, show as accurately as necessary our relative position. Such diversities of build and equipment so much affect the specific numbers under each head, that at best we can only obtain general notions. The vagueness of the terms frigate and corvette must be remembered. We have now the elements of a magnificent navy,—one that will no longer be mistaken for a mere steam fleet depending on fuel. It has been during the past twenty years loudly and industriously circulated throughout Europe, with evident satisfaction to some of the nations of Christendom, that the glory of England was on the wane—that her prestige was gone—that steam had levelled her to the scale of other countries possessed of coal and iron,

The following tables show the armament, and the nature of special services employed on:—

1. THE EFFECTIVE LIST.

STEAM SCREW.	GUNS.	PADDLE.	SAILING.

3 " sheer hulks.	125
2 " juvenile reformatories.	

and that steam had bridged over the Channel. But a sight of the above tables ought to induce a belief that the sovereignty of the seas is still in our hands.

It has been the practice in the British navy to dismantle ships when out of commission, and to keep them in the state of hulks until their services were again required.

A ship is called into active service, or "commissioned," by the appointment of a captain or commander to her, and his pendant being hoisted to announce the fact of her being placed under the Articles of War, she was taken to an appointed dockyard for refitting, manning, arming, &c., and in the course of a few weeks reported ready for sea. Hence, when sudden emergency arose, considerable delay in refitment postponed the time at which the services of the ship could be available to the country.

In 1844, however, the Firebrand, paddle-steamer, being out of commission at Portsmouth, was advanced so as to be considered a "reserve" ship. Gradually from that period, but by very slow and unequal steps, what is now called a *steam reserve* had been increasing, until in 1856 such reserve became a most valuable system, and extended from Portsmouth to Plymouth and Sheerness. As our ships of war are altered for steam-power, they, as well as new ships, are placed in the nearest steam-reserve. In this reserve force the effective unemployed ships are arranged as under, in four divisions:—

The first division consists of such ships, of every class, as are ready for sea within a day or two after being commissioned, so far as masts and rigging and all fittings are concerned, including guns, anchors, cables, shot, tanks, &c., together with all machinery, which in trial trips and periodical examinations by an inspector of machinery afloat has been properly tested and duly reported on, through the captain of the steam reserve, and from him to the commander-in-chief and the Admiralty. But powder and provisions are only shipped when about to proceed to sea.

The second division consists of such ships of every class as are fitted with engines, anchors, cables, shot, and tanks, but have neither masts, guns, powder, nor provisions on board. These will also have been tested in trial trips.

The third division comprises ships of any class which have their engines on board, but are without masts, guns, shot, tanks, anchors and cables, powder or provisions.

The fourth division are those ships which are in mere "ordinary," being in various stages of incipient preparation for advancement.

Not only does this arrangement provide ships to meet the sudden demands of diplomacy, but it affords a reserve of available subordinate officers for immediate sea service. In no branch of usefulness is this of more importance than as regards officers of engineers and warrant officers, who are attached to the guard-ship of each steam-reserve, and are subservient to all the discipline and usages of the service. Much remains to be done and is in progress, such as the providing means for the training of young engineers of the reserve, and also of boys who enter the navy; so that instead of sending raw recruits into the sea-going ships, boys are sent who, after about a year's training in the reserve school-ship, are fit to commence the career of a British sailor as "first-class boys." At present Sheerness is the only reserve port at which the educational movement has been tried on a large scale. The school-ship at that port is considered a model and an example for imitation. The long-wanted means for enabling young engineer officers to prepare for their examinations, has been here met with abundant advantage to them and to the service. There is also in the ship a school for the education of the children of engineers and warrant-officers of the steam reserve.

The government of the navy is vested in the lord high admiral, which office has been in commission since the Revolution, with the exception of two short periods, 1707-8 and 1827-8, when it was held respectively by Prince George of Denmark and the Duke of Clarence, afterwards King William IV. At present the Board consists of a first lord, who is a member of the cabinet, and five junior lords. By their orders all ships are built, sold, or broken up, commissioned, employed, and paid off. All appointments and promotions are made or approved by them; all honours, pensions, and gratuities are granted on their recommendation. All orders for the payment of naval moneys are made by them; they prepare the navy estimates, and lay them before parliament. The civil departments of the Admiralty are directed by the surveyor of the navy, accountant-general, storekeeper-general, comptroller of victualling, and physician-general.

The navy is composed of two bodies of men—seamen and marines.

There are commissioned, warrant, and petty officers.

The commissioned officers are flag-officers, captains, commanders and lieutenants.

Flag-officers are divided into the following classes, and rank and command in the order here following:—

Admirals of the fleet.

Admirals of the red, white, and blue squadrons.

Vice-admirals of the red, white, and blue squadrons.

Rear-admirals of the red, white, and blue squadrons.

There are superannuated and retired rear-admirals, who enjoy the rank and pay, but do not rise.

The admiral of the fleet, when in command, bears the union flag at the main-top-gallant-mast. The other flag-officers bear a square flag of

the colour of their squadron at the main, fore, or mizen top-gallant-mast, according to their rank.

The flag-officer holding the chief command of a fleet or squadron employed within certain geographical limits, termed a station, is called a commander-in-chief. He is responsible for the efficiency and conduct of the fleet under his orders; he disposes of the vessels composing it in such manner as will be most advantageous for the service; but without some especial necessity he is never to send one beyond the limits of his station. All vacancies in ships under his orders which are caused by death or dismissal from the service by the sentence of a court-martial, are in his gift.

A temporary rank is given to captains called commodore: they are of two classes, the first class having the pay and allowance of a rear-admiral, with a captain under him. They bear a broad pendant, but must strike it in the presence of a senior captain. Captains and commanders are appointed to command her Majesty's ships, except when the latter are appointed to flag-ships and ships of the line, in which case they must have served three years in command of a sloop or as first lieutenant of a rated ship.

When a captain or commander is ordered to commission a ship, he does so by hoisting a long pendant, having a St. George's cross on a white field next the mast, and a fly of the colour of the admiral's flag under whose orders he is placed. No vessels, except such as belong to her Majesty, or are hired for her service, and commanded by a naval officer, are entitled to wear this pendant. The ship being commissioned, a hulk or receiving ship is allotted for the use of the crew while fitting for sea; a party of marines, commanded in rated ships by a commissioned officer, is sent on board; seamen are entered as they volunteer, on being reported fit for the service after examination by the surgeon; stores are demanded as required, and the sea-stores, provisions, and water stowed away. When ready for sea, the ordnance and powder are received on board; the crew are paid two months' wages in advance; and the ship only waits the sailing orders from the Admiralty to proceed to her destination. The duty of the captain as regards the books and accounts is regulated by Act of Parliament; but the interior arrangements and discipline depend mainly on himself, in which he has for his guidance the Act 22 Geo. II., called the Articles of War, and the general printed instructions issued by the Admiralty. All muster and pay books, &c., are signed by the captain, commander, or senior lieutenant, master, and purser, or other officer in whose charge the stores in question may be placed.

The senior lieutenant is nominated by the captain, and has under his direction the whole management and superintendence of the internal arrangements of the ship; indeed on the qualifications of this officer must in a great measure depend the state of discipline and efficiency. The other lieutenants take the watch by turns, during which time they have charge and command of the ship; they are never to quit the deck without being relieved. The watches are periods of four hours, except that from four to eight P.M., which is divided into two, called the dog-watches. No mate is eligible for the rank of lieutenant until he has served six complete years in the navy, has completed his nineteenth year, and passed in seamanship and navigation.

The master has charge and stowage of the holds; a general charge of stores and store-rooms, over the gunner, boatswain, and carpenter; and navigates the ship under the directions of the captain. Secretaries are appointed by the flag-officer whom they serve.

Chaplains must be in priest's orders of the Church of England.

The paymaster has charge of the provisions, and the issuing of them, also of the slop clothing, soap, and tobacco; he enters into a penal bond with sureties for the honest discharge of his duties.

Mates are midshipmen who have passed the examination qualifying them for the rank of lieutenant.

Gunners, boatswains, and carpenters must have served a complete year as petty officers before they can be promoted. The gunner has charge of all ordnance stores; the boatswain, of all the sails, rope, and rigging; the carpenter, of all stores in his department, and is also to see the ports secure and water-tight, and to sound the well daily, and have the pumps in order for service. [GUNNER, NAVAL; BOATSWAIN; WARRANT OFFICERS, &c.]

In the event of the command of a ship devolving on petty officers, they are to take rank and command as they stand in the table of pay, except the following, who are not to take command:—

Schoolmasters, Clerks,	Masters-at-arms, Ships'-corporals.
---------------------------	---------------------------------------

Midshipmen cannot enter under twelve years of age nor above fifteen; they are appointed by the Admiralty. They have no specific duties.

By an Admiralty order, 23rd Feb., 1857, young gentlemen can enter the Royal Navy, as naval cadets, between the ages of thirteen and fifteen, being required to pass a previous examination at the Royal College, Portsmouth. After eighteen months' study they are eligible for promotion as midshipmen on passing another examination. A midshipman of eighteen months' standing has again to pass examination at the College, and if successful, he is eligible, after two years further service as midshipman, to the rank of mate.

All commissioned officers below a captain, midshipmen, also naval

cadets, and schoolmasters, must pass the requisite examinations to qualify them for their respective posts.

Petty officers are rated as far as possible from the leading seamen. They are ranged into classes thus—

Chief petty officers, who wear as a badge } on the arm }	The crown and anchor encircled with laurel.
First-class working petty officers, ditto	Crown and crossed anchors.
Second ditto ditto	Crown and anchor.
Leading seamen wear	Anchor.

N.B.—Seamen are also allowed increased pay for continued good conduct, and wear chevrons of gold lace on the arm, according to their merit.

The enlistment of boys has recently undergone a change highly beneficial to the service. Second-class boys are entered for continuous service for ten years, but only with consent of parents and guardians.

The following abstract shows the daily allowance of provisions to every person in the fleet:—

Fresh meat, 1 lb.	Soft bread, 1½ lb.
Vegetables, ½ lb.	Rum ½ gill.

When the above are not issued, the following:—

Salt beef, ¾ lb. } and } alternately { Salt pork, ¾ lb. Flour, ¾ lb. } and { Biscuit, 1¼ lb. } Pease, ½ pint. Cocoa, 1 oz. Vinegar, ½ pint } weekly. Tea, ¼ oz. Oatmeal, ½ pint } Sugar, 1½ oz.

A portion of the flour may be exchanged for a proportion of suet and raisins; and after 14 days at sea on salt provisions, lemon-juice is allowed in addition.

The pay of officers and seamen has recently undergone some modifications, but as it is stated that further alterations, to the advantage of every class, are still in contemplation, we refer for the present scale to the 'Navy List,' published periodically, where the actual scale is given in full detail. In a supplement to the 'London Gazette' of Friday, August 3, were issued the following regulations in reference to retiring pensions:—

All captains who have attained, or shall hereafter attain the age of sixty, without having served in their present rank, to be placed on a retired list, and receive retired pay as follows:—

If on 10s. 6d. half-pay list when retired,	18s. per diem.
If on 12s. 6d. " "	20s. " "
If on 14s. 6d. " "	

Captains who may arrive at the head of the list, without having served in that rank, to be placed on the list of reserved flag officers, with the pay of 23s. per diem.

Captains now on the 14s. 6d. half-pay list not to be affected by these arrangements unless by their own desire.

All commanders on the active list who have attained the age of sixty, or who may hereafter attain that age, to be placed on a retired list with the rank and title of retired captain, and to receive half-pay according to their length of sea service on the scale hereinafter mentioned.

Total sea service in the rank of— Commander and Lieutenant.	Pay per diem.
Under 3 years	Half-pay they may be receiving at the time when retired.
Above 9 years' and less than 12 years' service	10s. 6d.
Above 12 years' and less than 15 years' service	12s. 6d.
Above 15 years' and less than 20 years' service	14s. 6d.
Above 20 years' service	16s. 6d.

Lieutenants on the active list, who have attained, or who may hereafter attain, the age of sixty, to be placed on a retired list with the rank of retired commander, and to receive pay according to their sea service.

Total sea service in the rank of— Lieutenant.	Pay per diem.
Under 6 years	Half-pay they may be receiving at the time when retired.
Above 6 years' and less than 9 years' service	7s. 0d.
Above 9 years' and less than 12 years' service	8s. 6d.
Above 12 years' and less than 15 years' service	10s. 0d.
Above 15 years'	11s. 6d.

Time served in command of revenue vessels to count as sea time.

Time served in the coast-guard on shore, or in the transport service on shore, to count as sea time in the scale of retired pay, in the proportion of three years in the coast-guard, or transport service, as one of sea service.

Time served as mail or transport agents afloat, or abroad, to count for the same purpose as sea time for the first three years, and after

then in the proportion of three years' agent's time as two of sea service.

For every year's service as acting lieutenant, mate, or passed midshipman, after the completion of two years' service or combined service in those ranks, an officer to be allowed 3*d.* per diem additional.

Greenwich Out-pensions.—All officers on the active list who accept the out-pension of Greenwich Hospital to be placed on the retired list of the rank which they may hold; and to be permitted to assume a step in rank on reaching the age of sixty, but without further increase of pay.

1. All officers retired under this scheme to be eligible for the out-pension of Greenwich Hospital for the rank that they held on the active list, provided that they shall have served the following periods of commissioned time afloat:—

Captains, 15 years, including time as commanders and lieutenants.

Commanders, 12 years, including time as lieutenants.

Lieutenants, 9 years in that rank.

2. Officers who have received, or who may hereafter receive, severe wounds in action, or disabling hurts on actual service, are to be exempt from the above rule respecting time of service.

3. Officers on the existing reserved and retired lists or captains or commanders to be eligible for the out-pension of Greenwich Hospital, on the conditions stated in articles 1 and 2 of this section.

4. The regulations laid down in the scheme of retirement respecting time served in the coast-guard, transport, or mail service, to apply to the time required to be served for Greenwich out-pension.

The following pensions will be allowed to the widows of officers retired under this scheme, namely:—

- | | |
|--|----------------------|
| 1. Captains of 3 years' standing and upwards | 90 <i>l.</i> a year. |
| 2. Captains under 3 years' standing | 80 <i>l.</i> " |
| 3. Commanders retired with the rank of captain | 75 <i>l.</i> " |
| 4. Lieutenants raised to the rank of commander | 60 <i>l.</i> " |

We will now turn to that noble establishment and asylum for worn-out and disabled seamen, Greenwich Hospital. The revenue of the hospital is about 150,000*l.* a-year. The establishment consists of a governor, lieutenant-governor (both flag-officers), four captains, and eight lieutenants, residing in the hospital. There are about 2710 in-pensioners, and 120 matrons and nurses, all of whom must be seamen's widows.

There are two schools at Greenwich, called the Upper and Lower Schools.

The Upper School comprises two classes:—

1st. One hundred sons of commissioned and ward-room officers of the Royal Navy and marines.

2nd. Three hundred sons of officers of the above or inferior rank, and of private seamen and marines who have served or are serving her Majesty, and of officers and seamen of the merchant service.

They are admitted from ten to eleven years of age, under certain regulations, and are subject to the same discipline, diet, education, clothing, and destination. At the age of fifteen, or sooner, if the course of education be completed, they are sent to sea in the queen's or merchant service, or otherwise disposed of.

The Lower School consists of 400 boys, the children of warrant and petty officers, seamen and non-commissioned officers and privates of marines, who have served or are serving, or have lost their lives in the service of her Majesty. They are admitted from nine to eleven years of age, and quit at fifteen, the boy being sent to sea; any unprovided for at fifteen are sent to their parents or guardians. Any boy may be removed from this to the Upper School on obtaining a presentation, if not more than eleven years old, and possessing character and abilities.

Prizes taken by naval officers are the property of the captors, according to a certain scale, varying with the rank. There are ten classes of which second-class boys are the lowest, having only one share, and flag-officers the highest.

When any of her Majesty's ships carries bullion or jewels or freight, the captain or commander is allowed a per centage, regulated by the queen in council, as compensation for the risk and charge, one-fourth part of which is given to Greenwich Hospital, one-fourth part to the commander-in-chief if he shares the responsibility, and the other half to the captain.

Officers settling in the Australian colonies are allowed a remission of the purchase-money, in amount from 100*l.* to 300*l.*, according to their rank and length of service.

NAZARENES. It appears from many parts of the New Testament, that the majority of the Jewish converts to Christianity continued to observe the precepts and ceremonies of the Mosaic law. The destruction of Jerusalem by Titus was the cause of many of the Jewish Christians laying aside their peculiar customs; and from this time those Christians who continued to preserve the Mosaic law appear to have received the name of Nazarenes and Ebionites. [EBIONITES.] These two sects, though frequently confounded, differed in many essential particulars; the Ebionites held many erroneous opinions on some of the leading doctrines of the Christian faith, while the former only differed from the orthodox in maintaining that Jewish Christians were bound to observe the Mosaic law as well as the precepts and commandments of the Christian religion. The early fathers do not

appear to have regarded the Nazarenes as heretics, indeed the name was applied commonly to all the disciples of Christ. This may be the reason why we find no mention of them till the fourth century, when they are named, for the first time, by Epiphanius, and when it is asserted they have some peculiar opinions as to the divinity of Christ. On the gospel of the Nazarenes, see GOSPEL.

(Burton's *Lectures on the Ecclesiastical History of the Second and Third Centuries*; Mosheim's *Ecclesiastical History*, vol. i.)

NE EXEAT REGNO, is a writ which issues out of Chancery on the application of a complainant, to prevent his debtor from leaving the realm, being, in short, the *capias* of the Court of Chancery. It is directed to the sheriff of the county in which the debtor is; and commands him to cause the debtor to give sufficient bail or security, in the sum of—*l.*, that he will not go, or attempt to go, into parts beyond the seas, without leave of the court; and in case he shall refuse, to commit him to prison until he shall do it of his own accord, &c.

The writ cannot be applied for unless in a suit, that is, unless a bill is already filed; but a plaintiff may apply for it in any stage of a suit, whether the writ is prayed for by the bill or not. There must be a *debt in equity* actually due at the time when the writ is applied for; for the writ is not obtainable for a demand on which a party can be held to bail at law. The affidavit must also show that the defendant is going abroad, or it must show facts which prove that conclusion, and that the debt will be in danger if he quit the realm. The writ may be moved for *ex parte*, and issues until answer or further order. A defendant may apply to discharge the writ on putting in his answer.

This writ is founded on the real or supposed prerogative of the king to restrain his subjects from departing from the realm. The "*Natura Brevium*" contains two forms of writs, one of which has for its object to restrain a clergyman from going abroad without the king's licence; and commands the sheriff to take security from him or commit him to prison; the other has for its object to prevent a layman from going abroad without the king's licence; but it requires no security from the party, and differs in several other respects from the other writ. These writs are both entitled *De Securitate Inveniendi*, &c., and seem to be in substance, though not in name, writs of *Ne Exeat Regno*. From the former the present writ seems to be derived.

It is said that the object of the writ, as applied to clergymen, was to prevent them from having frequent intercourse with the Papal see. Whether the prerogative on which these writs were founded was a usurpation on the part of the crown or not, is a matter which has been somewhat discussed. The opinion that such a power as that which is exercised by this writ, "appears to have been unknown to the ancient common law, which, in the freedom of its spirit, allowed every man to depart the realm at his own pleasure" (Beames), is a vague surmise, expressed in language equally vague.

(*A Brief View of the Writ Ne Exeat Regno* by Beames.)

NEAP TIDES. [TIDES.]

NEBULÆ. A class of objects in the sidereal heavens, distinguishable by a dim light and the absence of any definite outline. The earliest notice of nebulae is to be found in the '*Syntaxis*' of Ptolemy, who has inserted five objects in his catalogue under the appellation of *cloudy stars*. The application of the telescope to astronomical observation revealed the real nature of the earlier nebulae. It was found that in every instance they really consisted of an aggregate number of stars, apparently so close to each other that they failed to produce an impression of their individual existence upon the eye. In 1614, Simon Marius discovered a nebula in the constellation Andromeda, which seemed to be of a totally different nature to any of the nebulae hitherto discovered, inasmuch as when observed in the telescope it was found to be irresolvable into stars. Its discoverer compared the aspect presented by it to that exhibited by the light of a candle when viewed through a transparent horn. In 1618 a similar object was discovered in the constellation Orion, by Cyxatus, a Swiss astronomer. Huyghens, who recognised this nebula in 1656, without having been aware of its previous discovery, was struck with amazement at its singular aspect. The region in the vicinity of the nebula being intensely black, he conceived that the phenomenon was occasioned by looking through an aperture in the heavens into the luminous region beyond.

About the middle of the last century, the number of nebulae discovered by astronomers amounted to little more than twenty. In 1755, Lacaille, the French astronomer, announced to the Academy of Sciences the existence of 42 additional nebulae in the southern hemisphere. He divided them into three distinct classes. The first class comprised those objects which, when viewed in the telescope, were found to retain their nebulous aspect without affording any indication of sidereal structure. The second class consisted of such nebulae as were resolvable by the telescope into stars. The third class consisted of stars surrounded by a nebulous substance. Messier, another French astronomer, was the discoverer of no fewer than 103 new nebulae. His observations are recorded in the '*Memoirs of the Academy of Sciences*' for 1771, and in the volumes of the '*Connaissance des Temps*' for 1783 and 1784.

The elder Herschel was the next astronomer who contributed towards the existing knowledge respecting nebulae. In 1786 he communicated to the Royal Society a catalogue of 1000 new nebulae. This was followed by a second catalogue, communicated to the same Society in

1789, and containing 1000 additional nebulae. In 1802, he communicated a third catalogue of nebulae, containing 500 new objects. On this last occasion he distributes the various objects of the stellar regions into twelve distinct classes.

I. *Insulated stars*, such as Arcturus, Capella, Sirius, &c.

II. *Binary stars*, or in other words, systems of two stars revolving in each case about their common centre of gravity.

III. *Triple and Multiple stars*.

IV. *Clustering collections and the Milky Way*. Herschel was of opinion that in many parts of the heavens the stars afford indications of collecting together and forming distinct clusters from the effect of their mutual attraction. He supposes that the Milky Way is undergoing a process of disruption from this cause.

V. *Groups of stars*. This consisted of aggregations of stars which did not exhibit any regularity of outline, nor condensation in any part of their structure indicative of their forming separate systems.

VI. *Clusters of stars*.—These were objects of a round form, presenting in all cases a gradual condensation towards the centre.

VII. *Nebulae*.—These were supposed to be objects consisting in reality of aggregate collections of stars.

VIII. *Stellar nebulae*.—These were imagined by Herschel to be clusters of stars situate at such immense distances as to put on the aspect of merely luminous points with burs.

IX. *Milky nebulousity*. This class consisted partly of aggregate collections of stars which were nebulous only in appearance, and partly of objects of a purely nebulous substance, like the nebula of Orion.

X. *Nebulous stars*.—These were stars surrounded by a nebulous atmosphere.

XI. *Planetary nebulae*.—This class consisted of nebulae of a perfectly round form, exhibiting a resemblance to the planetary bodies of the solar system, only they shone by a very pale light.

XII. *Planetary nebulae with centres*.—The aspect exhibited by these objects suggested the idea of a gradual condensation of the nebula into a single luminous point.

In 1811, Herschel communicated to the Royal Society a paper, in which he explained his views of the transformation of nebulae into stars. He endeavoured to prove that the nebulous substance, which his observations indicated to be extensively diffused throughout the sidereal universe, had a tendency to form into distinct aggregations of matter, in consequence of the mutual attraction of its particles, and that the resulting mass in each case by a process of gradual condensation finally acquired the consistency of a solid body. More recent observations of nebulae have not served to confirm this bold hypothesis.

In 1833, the younger Herschel communicated to the Royal Society a paper, containing the results of a re-observation of the nebulae of the northern hemisphere. These results are embodied in a catalogue containing 2306 nebulae and clusters, of which about 500 were discovered by himself. In 1828, Mr. Dunlop communicated to the Royal Society a catalogue of 629 nebulae and clusters observed in the southern hemisphere; and in 1847, the younger Herschel published the results of his astronomical observations at the Cape of Good Hope which, besides various other objects of importance, contained a catalogue of 1708 nebulae and clusters observed in the southern hemisphere.

The most recent contribution to nebular astronomy is due to Lord Rosse, who in 1850 communicated to the Royal Society a paper, containing the results of observations made by him, chiefly with his celebrated six foot reflector. One of the most remarkable facts disclosed by these observations consists in the spiral arrangement of several of the objects. It appears also from them, that many nebulae which had been previously considered as irresolvable objects, consist of agglomerations of stars, and the conclusion naturally suggested by such observations is, that all nebulae are in reality nothing more than aggregate masses of stars, which merely require telescopes of adequate power to reveal their true structure.

NECESSITY. [FREE WILL.]

NECRO'SIS (from *νεκρός*, "dead,") is the term applied particularly to mortification or death of bone. Its general causes and the mode of reparation are the same as those of mortification generally. [MORTIFICATION; INFLAMMATION; BONE.]

NEEDLE MANUFACTURE. This branch of industry is supposed to have originated in Spain, from the circumstance of the name *Spanish needles* being originally used in England, although the art was brought here from Germany. Needles were first made in England about the year 1565, by Elias Crowse or Krause, a German, who settled in London; or, as others say, by a Spanish negro, who refused to reveal the secrets of his art. The manufacture was lost to England for nearly a century, but recovered about 1650, by Christopher Greening, who settled at Long Crendon in Buckinghamshire. The reputation long enjoyed by *Whitechapel needles* points out the particular locality in London where the manufacture was once carried on. At the present time, the largest numbers of needles are made at Redditch in Worcestershire, at Hathersage in Derbyshire, and in and near Birmingham.

The manufacturing processes are as follows:—The steel is procured from the Sheffield or Birmingham wire-drawers, in coils of 12 lb. or 14 lb. of wire. The usual sizes of sewing needles vary from $\frac{1}{32}$ to $\frac{1}{100}$ of an inch, and the wire is selected of corresponding thickness. The wire is

cut into lengths equal to two needles; and these lengths, being placed together in a bundle, are brought to a glowing heat, and bound together by means of iron rings from three to seven inches in diameter, placed at each end of the bundle. This bundle is then placed on a cast-iron table, and rolled to and fro upon it, under the pressure of a flat bar of iron, by which means the wires are made perfectly straight. Several of these wires are then taken by the grinder, and together are pointed on a small dry grindstone. This process requires considerable dexterity for its proper accomplishment, as each wire must be so held by the grinder as to revolve in contact with the grindstone. It is this dry-grinding which makes the trade of a needle-grinder so injurious to health, through the inhaling of the small particles of steel which are thrown off during the operation. A preservative against this evil has been provided: this consists of a mask of magnetic wire-gauze, worn so as to protect the mouth: the particles of metal, being attracted by this means, are prevented from passing into the lungs. It is but seldom however that the grinders can be induced to wear these masks. Needle-grinding is a well-paid but destructive employment; some men can grind 10,000 in an hour.

When the pointing (at both ends) is finished, the holes or eyes are perforated. This operation (on the hand method) is usually performed by females. The tools employed are, a small anvil fixed on the work-bench, a hammer, a finely-pointed and well-tempered steel punch, a pair of plyers, a file, and a block of lead. The woman makes an indentation on one side by means of the punch and hammer; the needle is then taken from the anvil, and being placed with the indented side downwards on the block of lead, the perforation is completed by striking with the punch and hammer on the opposite side of the needle. Holding then the needle in the plyers, the head is somewhat bent, and with the file the *guttering* is performed, which is the forming of the channel that may be seen on each side where the perforation is made. The head is then smoothed by passing the file over it. Needles to which the name drilled-eyed is applied are perforated in the manner here described, but the additional process is used of smoothing the eye by means of a drill after it is perforated. In this hand method, the wire is cut into two before the perforating, and the end of each piece is slightly flattened with a hammer before the punch and drill are employed.

Machines, however, at first used for large needles, are now generally used for all sizes. The wires, each about three inches long if to form needles known as No. 6, are subjected to a stamping machine, in which a weight of 30 lbs. is brought down to stamp the gutter on each side of the needle, and to make an indentation partly through the wire; this is done at the rate of 4000 wires in an hour. A small hand-press, worked by boys, then drives each indentation right through the wire, thus making perforations for the eyes of two needles. In *fig. 1*, *bb* is

Fig. 1.—Piercing Needles.

the double needle, resting on the anvil *a*, held in its place by *d*, and pierced by *c*. The wires are then "spitted;" that is, two fine wires are made to pass through the two eyes of several dozens of them, to hold them while a man files off the burr left by the stamping. The workman then bends and works the comb of wires to and fro between his hands, until he breaks each wire into two, leaving an eye or perforation to each half. *Fig. 3* shows five different stages of the needle, up to the point where the wire is just about to be severed into two and magnified representations of the last three of those stages. The filer and two spitters prepare 4000 needles in an hour.

These operations being performed when the steel wires are in a soft state, the wires become more or less bent, and must be straightened, which is done by rolling them on one plate of metal by a smaller plate dexterously handled; this is called *soft-straightening*. The needles are then placed, many thousands together, in a kind of crucible, and covered over with ashes; after which they are put into a close furnace

and exposed to a cherry-red heat. When this degree of heat has been attained, the crucible is withdrawn, and the needles are dropped into cold water or oil; from this they are taken out and put upon an iron

Fig. 2.—A Comb of double-needle wires.

plate almost red hot, where they are turned about so as to cause the heat to apply equally to all; and as fast as the needles become of a blue colour, they are removed as being of a proper temper.

Such of the needles as now appear crooked are straightened on a small anvil by blows from a hammer: a process conducted by women, and called *hammer-straightening*.

The needles are next ranged in parallel rows upon a coarse cloth, which has been smeared with a mixture of oil, soft soap, and fine emery powder. In this cloth from 40,000 to 50,000 needles are rolled up, and twenty or thirty of these rolls are placed together in a machine like a mangle. The rolling to which they are here subjected is continued, by means of steam or water power, for two and sometimes three days, during which time the cloth wrappers being worn out, require to be once or twice replaced by new ones. The finest needles require forty hours of this kind of friction. When taken out, after rolling, the needles are perfectly bright.

Fig. 3.—Successive stages of a Needle.

The excellence of modern needles consists, in part, in the process of *drilling*, to which the best kinds are subjected. When the eyes of needles are only stamped and pierced, their edges are apt to cut the thread; but by a subsequent drilling, the eye becomes as smooth and polished as any other part. To effect this, the needles are *blued*, or heated to a particular temper; then *countersunk*, to bevel the edges of the eye; then *drilled* by means of delicate wires which pass through the eyes; then *ground* on small revolving gritstones, to give roundness to the head of each needle; and then *polished* by pressure against revolving wooden wheels covered with buff-leather, and touched with polishing paste. The different stages in these highly-finished needles are shown in fig. 4.

The needles, whether of the finer or commoner kinds, are now examined for the rejection of any that may be imperfect; and then shaken in a flat tray until all become parallel. But, though parallel, they are not regular; seeing that the heads of some are in one direction, and those of others in another. They are brought into regularity in a simple but remarkable way. A girl, seated at a window, spreads out the needles before her, parallel with the window; by a

ARTS AND SCI. DIV. VOL. V.

delicate touch, aided by a quick eye, she draws out laterally to the right, those which have their eyes on the right, and to the left, those

Fig. 4.—Drilled-eyed Needles.

which have their eyes on the left; and then combines the two parcels. Women then separate the needles into parcels of 25, and wrap them up in blue papers—at the rate of 3000 needles in an hour. Labels are pasted on the papers and dried; 20 papers are packed into a parcel; and from 10 to 50 parcels are made up into a bundle, for the wholesale trade. If for exportation, the bundles are placed in soldered tin boxes. A bundle of 10,000 needles, of the kind called No. 6, forms a compact mass 6 inches long, $3\frac{1}{2}$ wide, and 2 in thickness.

Redditch, which was only a village a few years ago, is now a considerable town, almost all the inhabitants of which live by the needle trade. Eight or ten thousand persons are employed in the works in the town and neighbourhood; and these support the bulk of the remaining part of the population. The work is conducted on two different systems, the factory and the domestic. On the factory system a large building is constructed, supplied with steam or water power, and with efficient machines of all kinds; and in this building all the processes are conducted. On the domestic system, country people, living within a few miles of Redditch on all sides, come to the warehouses or manufactories in the town, fetch away a packet of wires or needles, take it home, do a portion of the work, and return the packets to the warehouses. Some do the annealing, some the pointing, some the piercing, some the drilling, &c.; each person, (of whom more than half are females) being competent for only one branch of the manufacture. The product of the whole neighbourhood, even several years ago, was supposed to reach 100,000,000 needles per week!

NEGATIVE QUANTITIES. This subject is considered, as a part of the most complete algebra, in the article ALGEBRA. In the present article we confine ourselves to such a view as may be sufficient for ordinary algebra.

In the oldest treatises on algebra which exist, there is mention of a modification of quantity unknown in arithmetic, called *negative quantity*, as distinguished from *positive*. In the Viga Ganita [VIGA GANITA, BROS. DIV.] we find this distinction and the rules for its use precisely as in modern treatises. One of the commentators says that negation is contrariety; and the 'Liliwati' contains the geometrical interpretation of a negative line—namely, a line measured in the direction contrary to that of a positive line. The commentator says that Patna is fifteen yojanas east, and Allahabad eight yojanas west, of a place called Varanasi; "the interval or difference is twenty-three yojanas, and is not obtained but by addition of the numbers. Therefore, if the *difference* between two *contrary* quantities be required, their *sum* must be taken." Surely it will be said that algebra began in a strange confusion of ideas; but yet the fault is rather in expression than in conception. An art was in existence presenting undoubted means of discovering truth, commencing with a generalisation of which the use was obvious, but not the meaning. In Diophantus we find the common rule announced as a definition (without even a previous notice of the distinction of quantities) in terms as broad as the following:—"Δεψις ἐπὶ λείψιν πολλαπλασιασθῆσα ποιεῖ ὑπαρξιν," &c.—literally, "Defect upon defect repeated, makes existence." In Mohammed Ben Musa [ALGEBRA] the rules are announced in the same way, though the separate existence of positive and negative quantities does not seem to be assumed: it must be remembered that this work was written for popular use. The European promoters of algebra, with the exception only of Vieta, adopted the use of two species of quantities, positive and negative, with the explanation above noticed. Vieta not only avoided the negative quantity, but, so far as he could, dispensed with subtractive terms and subtraction itself. He discards the double nature of quantities in the words "Plus autem vel minus non constituunt genera diversa."

It is not our intention to follow the earlier algebraists through their different uses of negative quantities. These creations of algebra retained their existence, in the face of the obvious deficiency of rational explanation which characterised every attempt at their theory. Newton and Euler distinctly admit the existence of the quantity less than nothing: the latter asserts that a man who has no property, and is in debt 50 crowns, would only have nothing if any one else made him richer by a gift of 50 crowns, and therefore begins with 50 crowns less than nothing. Elementary treatises for the most part try to append an explanation of negative quantities to an algebra which is

nothing more than arithmetic, instead of introducing those new abstractions which are the basis of the separate science: so that algebra, instead of being systematically learnt, is collected by slow and often dubious steps from arithmetical examples, in which the rules of operation of the former science are employed, preceded by the principles of the latter. Few, therefore, acquire a real perception of the meaning of the subject, except those who study mathematics to great extent. It is matter of notoriety that difficulties attend the beginner in algebra of a nature totally different from those which are found in geometry; so that while a person who has read a few books of Euclid may be imagined capable of writing an intelligent commentary on what he knows, another who has mastered a common elementary treatise on algebra is conscious only of a great increase of working power, with a glimmering of principles which owe their reception more to the never-failing accuracy of their results than to native evidence or logical deduction from easily admitted truths.

We must premise that, as in all other cases where the first principles of a science have been matter of dispute, it by no means follows that one view of the subject is the most easy to every mind. Something must depend on the intellectual constitution of the individual; and if this be most probably true in geometry, the remark applies with still greater force to algebra.

The first abstraction which meets us in arithmetic follows the transition from actual magnitudes (concrete numbers, so called) to their numerical representations. We then find general properties of numbers, in which we learn to consider number independently of a specific concrete unit. Thus we see in $7 + 5 - 3 = 7 - 3 + 5$ a relation equally true, whatever may be the nature or magnitude of the unit. When we drop the concrete number and rise to the abstract, we gain something more by the transition than immediately appears; and this the student should particularly note, because some of the succeeding difficulties which attend the passage into algebra are very similar in character, though preceded by a stranger and harder process. The operation of multiplication takes a power and a property which it had not before: thus if we denote concrete number by Roman numerals, and if we speak of yards, it is clear that $5 \times \text{VII} = \text{XXXV}$, or 7 yards taken 5 times is 35 yards. But we may not, therefore, say that $\text{VII} \times 5 = \text{XXXV}$, for $\text{VII} \times 5$, the number 5 multiplied by 7 yards [MULTIPLICATION], is an incongruous and unmeaning set of words, and it would be equally improper to say that it is and it is not 35 yards. In abstract numbers no such caution is necessary: 7×5 and 5×7 are both the same. If men had never considered number independently of magnitude measured or repeated by it, the arithmetician would have confounded $\text{VII} \times 5$ and $5 \times \text{VII}$, because he would soon have found that no false results would have sprung therefrom; while $\text{VII} \times 5$ would have been a sort of impossible quantity, useful in practice and difficult in theory.

We are now on the ground of abstract arithmetic, and on examining the four fundamental operations, we see no difficulty in either addition, multiplication, or division. So soon as we have mastered the subject of fractions, and have clearly admitted the introduction of a part of a repetition [MULTIPLICATION], we say as follows:—Let a and b be any two numbers or fractions, and $a+b$, ab , and $a:b$ must be real numbers or fractions, assignable by demonstrated operations so soon as a and b are assigned. But there is still a restriction upon the possibility of subtraction: $a-b$ has no imaginable existence, unless a be greater than b ; when $a=b$, the magnitude of $a-b$ vanishes entirely, and when a is less than b , the direction to perform $a-b$ is just the same as asking for a part which shall be greater than the whole of which it is a part. If we confined ourselves to particular arithmetic, in which all numbers used have specific values, it would most likely be thought of no use to carry the subject further, and in one point of view correctly; that is, it would be of little moment to deduce methods by which an individual so careless as to write down and operate upon such a symbol as $3-4$ might be enabled to arrive at a subsequent correction of the mistake which a glance at the symbol should show him he has made. But when we use general symbols of number, we are liable to mistakes of two kinds, both dependent upon our liability to invert the order of terms of which the less should be subtracted from the greater.

First, we may mistake the nature of the quantity which results: thus if it be part of the conditions of a problem that I pay £ a and receive £ b , and if the application of the conditions requires that I should state how much I gain or lose, the answer should be either a loss of £ $(a-b)$ or a gain of £ $(b-a)$, according as a or b is the greater. We have then the choice between adopting one of these with the chance of being entirely wrong, or of working the problem in two distinct ways. And if it should happen that the conditions of the problem present this alternative in six distinct instances (and sometimes it happens oftener), there would be no less than 64 cases of solution, all, arithmetically speaking, essentially different in the mode of obtaining the answer, whether the answers obtained be the same or different.

Secondly, we may make an error of the same kind in the details of operation. For instance, suppose we have $a+b-c$, which it is convenient to exhibit in the form of a altered by one single addition or subtraction. If we assume an addition, and write $a+(b-c)$, we may be in error; for if b be less than c , the proper alteration is $a-(c-b)$.

It is evident that both species of mistake are precisely of the same kind. Let us call them, for distinction, errors of interpretation and errors of operation, and let us show first that an error of interpretation will produce the error of operation and no other. If, in the first problem, we suppose $a-b$ to be lost where $b-a$ is really gained, and if the problem, for instance, require the result of the proceeding to be annexed to a loss x , we shall suppose there is altogether a loss of $x+(a-b)$, whereas it should be a loss of only $x-(b-a)$. Secondly, the error of operation will produce the error of interpretation, whenever any interpretation is made; for when we look at $x+(a-b)$ as a loss, we shall evidently suppose it to be more of a loss than x , or that $a-b$ is lost besides; whereas, had we looked at $x-(b-a)$, we should have inferred that there is a less loss than x . Now the first step of the young algebraist, before he attempts any transition from universal arithmetic to algebra, must be to examine by many instances the effect of both classes of errors upon the subsequent proceedings and results. We shall here only state the truths at which he will finally arrive, with an example of each. The beginner cannot, as the proficient may do, see a sufficient reason for these results in the common rules of algebraical operation; and we should doubt that anything but a large number of examples would serve to give him the necessary insight into the conclusions.

1. The mistake of operation, how often soever repeated, and how complicated soever the deductions which may be drawn from it, produces no result in any way different from that of the correct process; that is, its result can be reduced to the result of the correct process by the use of no more than those rules which apply in the rational process.

Thus if $x+a-b$, wrongly taken to be $x+(a-b)$, b being greater than a , be multiplied by $x+p-q$, wrongly taken as $x+(p-q)$, q being greater than p , we find as the (supposed) product

$$x^2 + (a-b+p-q)x + (a-b)(p-q),$$

to which the application of the common rules gives

$$x^2 + ax - bx + px - qx + ap - bp - aq + bq,$$

precisely the same as the product of $x+a-b$ and $x+p-q$. The reason of this is as follows:—In all the rational cases of the four operations, a term in the construction of which two signs are used has $+$ before it, if those two signs be alike, and $-$ if they be unlike, as in

$$\begin{aligned} a+b-(c-d), \text{ or } a+b-(0+c-d) \\ = a+b-c+d \\ (a-b)(c-d) \text{ or } (0+a-b)(0+c-d) \\ = 0+ac-ad-bc+bd. \end{aligned}$$

If then a term were subjected to the signs $++$, it would make no difference if the same term were subjected to the signs $+-$, for the effect of $--$ is the use of $+$. If then we take $x+a-b$ wrongly as $x-(b-a)$, we see that when we come to add this, say to c , we have

$$c + \{x-(b-a)\}$$

in which a , before it is disengaged, must come under the signs $+-$, or, if the phrase be less objectionable, under the application of the rules to these signs, successively. But the correct process would give

$$c + \{x+(a-b)\}$$

in which a falls under the application of the rules to $++$; and such application to $++$ gives the same result as that to $+-$, necessarily and demonstrably, though in one of the two applications there is the symbol of absurdity. In the same way the other cases may be proved, whence it follows that however many of these simple operations may be performed, no result can arise except either that of the correct operation or one which may be brought to it by the operations on signs, already described.

We must here pause to remind the reader that errors, however palpable and admitted, are not necessarily productive of error. True reasoning, on true principles, must lead to truth; but if for true we write false, and for truth falsehood, we have no longer any right to say *must*, but only *most probably will*. If then we can show of a particular class of errors that, used in a certain way, the results agree with those of true reasoning on true principles, we may demand the use of those errors as demonstrated means of finding truth. The mind of man would never stop at such a point; but, for all that, we have the conclusion, as a logical consequence of the rules of arithmetic, that the mistake of the impossible subtraction introduced in operations, and not having previously vitiated the interpretation by which the fundamental objects of operation (equations) were deduced from the conditions of the problem, will produce no falsehood in the result.

2. Let us now examine the consequences of the error of interpretation. The effect of this is, that we write $a-b$ instead of $b-a$, but at the same time we suppose the quantity of which we are thinking to be of a diametrically opposite character to that which it ought to have. But also at the same time we add this symbol where we should subtract it, and *vice versa*; so that where we should take $a-b$, and add, giving $c+(a-b)$, we make one mistake in taking $b-a$, and another in subtracting, giving $c-(b-a)$. When mere rules come to be applied, we find the same result from both, namely, $c+a-b$ and $c-b+a$. We might then so manage as to elude the actual presentation of the nega-

tive quantity, as in the following problem:—Two persons are now aged 50 and 40; at what date is (was, or will be, as the case may be) the first twice as old as the second? Let us suppose that we reach the date by going a years forward and afterwards b years back from the epoch to which we then come: here is a supposition which is perfectly competent to yield any result, before or after the present epoch, by properly assuming a and b . But we must now choose a supposition; let it be that the ratio in question exists at some future time, that is, a is greater than b . In $a-b$ years then the thing happens; consequently,

$$50 + (a-b) = 2 \{ 40 + (a-b) \} \quad \dots (1)$$

$$50 + a - b = 80 + 2a - 2b \quad \dots (2)$$

$$80 + 2a - 2b - 50 - a + b = 0$$

$$30 + a - b = 0$$

$$b = a + 30.$$

Or any number of years forward and 30 more years back is all the answer the conditions of the problem will give, or the event took place 30 years ago. But the correctness of this reasoning is only a semblance, for the result contradicts the supposition on which it was obtained, namely, that a is greater than b . To increase 50 by the excess of a over 30 more than a is beyond the power of the arithmetician. If then it be taken that a is less than b , or that the event happened $b-a$ years ago, we have

$$50 - (b-a) = 2 (40 - (b-a)) \quad \dots (3)$$

$$50 - b + a = 80 - 2b + 2a \quad \dots (4)$$

and (4) is the same as (2); so that we arrive at the same result as before, and find our conclusion to justify the supposition on which it was made. The steps (1) and (3) differ to the same effect as if an error of operation had been made on (4) or (2) in retracing the steps.

In the preceding, by the use of two symbols, a and b , we have enabled ourselves to obtain a correct and intelligible answer, even by the incorrect process, since we end with the determination of $b-a$ ($=30$), even where we reasoned on $a-b$. If however we had represented our unknown quantity by a single symbol, x , our first process would have stood as follows:—

$$50 + x = 2 (40 + x) = 80 + 2x$$

$$x = 50 - 80$$

And the answer is obviously impossible. Our second process is,

$$50 - x = 2 (40 - x) = 80 - 2x$$

$$x = 80 - 50 = 30.$$

From such instances as the preceding it may be collected that an error of interpretation, which causes us to write $a-b$ instead of $b-a$, will, in finding the value of $a-b$, cause an impossible subtraction to appear; and *vice versa*, that the appearance of an impossible subtraction in the result can arise from nothing but a primitive error of interpretation in fixing the nature of that result. This point must be well ascertained by every beginner from repeated instances.

Such a result as $3-8$ may be written $3-3-5$, or $0-5$; so that the error of attempting to subtract 8 from 3 is reducible to that of attempting to subtract 5 from nothing. At our present point we can say that the occurrence of $0-5$ shows us that the result which we supposed ourselves about to obtain was diametrically wrong in quality in our previous supposition: thus in the preceding problem we found $50-80$, or $0-30$, and the real answer is 30 in its magnitude, but instead of being, as we supposed, 30 years after the present time, it is 30 years before it.

Having arrived at this point, the earlier algebraists at once received such symbols as $0-5$ and $0-30$, which they wrote -5 and -30 , into the list of algebraical objects of reasoning, calling them *negative quantities*, and treating them as diametrically opposite in meaning to 5 and 30, which should for comparison be written $0+5$ and $0+30$. These they called *positive quantities*. And, because, in all possible subtractions the remainder is less than the minuend ($a-b$ is less than a) they called $0-5$ less than nothing. The fault committed by elementary writers, in beginning algebraical works by an exhibition of these definitions without the least warning of the manner in which arithmetical terms had been extended, converted the whole science into a mystery.

If we extend the notion of quantity so as to give different names to those of diametrically opposite kinds, we may call one set of quantities direct, and the others inverse. Thus property and debt, distance north and distance south, time before and time after, ascent and descent, loss and gain, progression and retrogression, &c. &c., are of different kinds; either of any one pair may be called direct, but the other is then inverse. And in circumstances which require the addition of the direct quantity, the subtraction of the inverse is equally required: thus whatever an increase in A's property will augment, a diminution of it will diminish; whatever distance on a line of progression on that line will increase, retrogression will diminish. If then we have $a+b$ where we imagine both quantities were what we took them to be; but if it should turn out that b is of the contrary kind, we know that we should have had $a-b$. If we put $+b$ for the quantity we thought we were using, and $-b$ for its opposite, the ordinary rule of signs will be

sufficient to make the conversions which the correction of the mistake requires. Thus if, attending only to the rule that like signs produce + and unlike signs —, we treat

$$a + (+b) \text{ and } a + (-b)$$

we find

$$a + b \text{ and } a - b;$$

or, in this instance, the affixing of + or — to a quantity according as our initial supposition is correct or incorrect, leaves us with our result if we were correct and makes the necessary alteration if we were incorrect. The application of the same reasoning leads to the same conclusion in all the cases of addition and subtraction. Observe also that if any one, disputing the propriety of making the signs + and — take a new meaning, should prefer, say, to denote direct quantity by the prefix of ¶, and inverse quantity by that of §, the rule he would arrive at by induction is that like signs produce + for operation, and ¶ for interpretation, while unlike signs produce — for operation and § for interpretation; here by like signs he would find he must mean + and +, or + and ¶, — and —, or — and §, and all others unlike. His final rule then would be, use ¶ as if it were +, and § as if it were —, so that he would ultimately differ from the algebraist by the continual use of two new signs without any new uses or practical meanings.

In the operations of multiplication and division the rule of signs is thus shown:—It is said that two negative quantities multiplied together produce a positive quantity, which means that a mistake of direct for inverse, or *vice versa*, made in both the terms of a product, produces no mistake in the product, when the latter is formed by the usual rules. Thus, if a , which should be $x-y$, has been taken to be $y-x$, and if b , which should be $v-w$, has been taken to be $w-v$, the algebraical product

$$(w-v)(y-x) \text{ or } wy-wx-vy+vx$$

at which we arrive in the mistaken process, is precisely the same as

$$(v-w)(x-y) \text{ or } vx-vy-wx+wy$$

at which we should have arrived in the correct process.

The first step then from arithmetic to algebra is made by the following definitions:—

1. Quantities are distinguished into positive and negative, which are to be considered as of diametrically opposite kinds; and common arithmetical quantities (abstract numbers without signs) are to be considered as positive. 2. The rules of arithmetical algebra are to be applied to the extended algebra, and in all cases in which the latter presents a case unknown to the former, the rule of signs already known in the former must be applied. The extension which takes place in the terms *less than nothing*, &c., will be considered under the word NOTHING.

The preceding extension gives an extended meaning to all the terms of operation; thus addition is no longer the simple arithmetical process, but a compound operation, first reducing a multiplicity of signs to one alone, and then following the direction of that sign; and the same of subtraction. Thus $a - (-b)$ is $a+b$. It may be asked then how we are to trace our steps through any problem so as to form its equation out of symbols which seem to have various meanings; for it might appear as if the + of algebra were either the + or — of arithmetic, as the case may be. The answer is very simple: since the extended algebra is no more than arithmetic in its actual operations, however the meaning of those operations may be extended, we may be sure that if we assign a particular case of a problem, and treat it entirely as in arithmetic, we are, though with one case only in view, performing upon limited symbols (limited because we think at the time only of a limited meaning) the same steps which we should have to follow if we could, by one act of the mind, grasp the symbols in their utmost generality.

NEGATIVE RADICALS. [ORGANIC RADICALS.]

NEGOTIABILITY. [BILL OF EXCHANGE.]

NEMEAN GAMES, one of the four great national festivals of the Greeks, derived their name from Nemea, a village in the north-eastern part of Argolis, on the borders of the Corinthian territory. They were celebrated under the presidency of the Corinthians, Argives, and inhabitants of Cleonæ (Scholiast. on Pindar); but in later times they appear to have been entirely under the management of the Argives. (Liv., xxxiv. 41.) They are said to have been celebrated every third year; and sometimes, as we learn from Pausanias, in the winter (ii. 15, § 2; vi. 16, § 4).

The Nemean games were (according to some legends) first established by the Epigoni, in memory of Opheltes (Schol. on Pind.; Apollod., iii. 6, 4; Paus., x. 25, § 2); others attribute their foundation to Hercules, in honour of Zeus, in consequence of his victory over the Nemean lion.

The games, at first of a warlike character, afterwards consisted of horse and chariot racing, boxing, wrestling, archery, and casting the spear. The crowns bestowed on victors were made of parsley [OLYMPIC GAMES.]

NEMESIS (Νέμεσις), a female Greek divinity, who appears to have been regarded as the personification of the righteous anger of the gods. She is represented as inflexibly severe to the proud and insolent (Paus., i. 33, § 2.); but she also sets right the inequalities of fortune, and

avenges wrong doing: in some respects Nemesis is the equivalent of conscience. According to Hesiod, she was the daughter of Night, by others she is called the daughter of Erebus. ('Theog.', 223; compare Paus., vii. 5, § 1.) There was a celebrated temple sacred to her at Rhamnus, one of the demi of Attica, about sixty stadia distant from Marathon. In this temple there was a statue of the goddess, made from a block of Parian marble, which the Persians had brought thither to erect as a trophy of their expected victory at Marathon. Pausanias says that this statue was the work of Phidias (i. 33, § 2, 3); but Pliny ascribes it to Agoracritus; and adds that it was preferred by M. Varro to all other statues which existed. ('Hist. Nat.', xxxvi., 4, § 3.) A fragment, supposed by some to be the head of this statue, was found in the temple of Rhamnus, and was presented to the British Museum in 1820: it is now No. 325, in the Elgin Saloon. The inhabitants of Rhamnus considered Nemesis to be the daughter of Oceanus. (Paus., vii. 5, § 1.)

The practice of representing the statues of Nemesis with wings was first introduced after the time of Alexander the Great by the inhabitants of Smyrna, who worshipped several goddesses under this name. (Paus., vii. 5, 1; ix. 35, 2.) She is often figured on ancient coins and gems, and sometimes with the attributes of Tyche. According to Müller ('Archäol. der Kunst,' § 398; and see 'Denkmäler der Alten Kunst,' Taf. lxxiv.), in early art Nemesis bore a strong likeness to Aphrodite: later there was more of symbolism in representations of her.

According to a myth preserved by Pausanias, Nemesis was the mother of Helen by Zeus; and Leda, the reputed mother of Helen, was only her nurse (i. 33, § 7); but this myth seems to have been invented in later times to represent the divine vengeance which was inflicted on the Greeks and Trojans through the instrumentality of Helen.

There was a statue of Nemesis in the capital at Rome; though we learn from Pliny that this goddess had no name in Latin. ('Hist. Nat.', xxviii. 5; xi. 103.)

NEOLOGY. [RATIONALISM.]

NEOPHYTES (from a Greek word which means "newly planted") is the appellation given to the converts to Christianity who have just received baptism. In the early church the Neophytes, after that solemn ceremony, wore white garments for eight days. They were also subject to a strict discipline or probation for a much longer period. The Jews, Mussulmans, or Pagans, who are converted to Christianity, are called Neophytes by the Roman Catholic missionaries, and there are houses at Rome and other places for their reception and instruction.

NEPHRITIS, inflammation of the substance of the kidney. Idiopathic nephritis is a very rare disease. When present more or less pain is felt in the region of the kidney, which is sometimes referred to the umbilicus. The pain also shoots along the ureters, and there is a sense of numbness down the thigh, and in the male there is often pain and retraction of the testicle. A frequent desire is felt to pass the water, which is sometimes pale, but more frequently of a deep red colour. There are nausea and vomiting, and the bowels are constipated. There are also the general symptoms of inflammatory fever. Sometimes the inflammation proceeds to suppuration, and then pus is found in the urine.

In this disease the kidney after death presents a softened structure, and the veins are loaded with blood.

Not only is the substance of the kidney subject to inflammation, but the mucous membrane lining the tubuli and the pelvis may be the seat of diffuse suppurative or ulcerative inflammation, and to this condition the name *pyelitis* has been given.

Inflammation of the kidneys is most frequently produced by the presence of a calculus in the pelvis of the kidney, an occurrence which is ordinarily called "gravel." Gravel may however exist without producing nephritis or pyelitis, but is usually accompanied by severe pain in the region of the kidneys which is called *nephralgia*. The deposits thus impacted in the kidney are of various kinds, which form calculi in the bladder and deposits in the urine after it has been passed. [URINE, MORBID STATES OF.]

Nephritis and pyelitis may be the result of stricture in the urethra which acts by preventing the free discharge of urine, and causes inflammation of the ureters, which extends at last to the kidney.

In the treatment of these diseases it is most important to ascertain and remove the cause. When there is pus in the urine, and the other symptoms of nephritis, the first inquiry should be the state of the urethra, and if stricture exists, it must be relieved. [URETHRA, DISEASES OF.]

In idiopathic nephritis the treatment must be directed to the reduction of the inflammation, and cupping over the loins; purgatives and opiates will be found most effectual, and time must be given for the passage of the concretions from the kidneys into the bladder, from whence they are discharged by the urethra.

NEPTUNE, the most remote of the known members of the planetary system. The discovery of this planet by means of an investigation founded on the perturbations which it produces in the movement of the neighbouring planet Uranus, must ever be regarded as one of the most brilliant feats in the annals of science. We proceed to give a brief sketch of the circumstances which led to this memorable achievement of pure theory.

Soon after the discovery of the planet Uranus by the elder Herschel in 1781, it was found that it had been observed as a star on several previous occasions by various astronomers who were unacquainted with its planetary nature. The earliest of these observations dates from the year 1690, and is due to Flamsteed. The remaining places of the planet were determined partly by the same astronomer, and partly by Le Monnier and Mayer. These early observations were found exceedingly useful for determining the orbit of the planet, subsequently to its discovery by Herschel. In 1821 Bouvard, the French astronomer, published new tables of Uranus, in the introduction to which he announced an unexpected result. He experienced no difficulty in satisfying the earlier observations of the planet by an elliptic orbit of determinate elements, nor in similarly representing the observations made subsequently to its discovery in 1781, but he found it impossible to include both sets of observations in the same orbit. He accordingly rejected the earlier observations of the planet, and constructed his tables exclusively on the basis of the more modern, leaving the discovery of the anomaly to future research. He appears to have suspected that the discordance was due to the disturbing action of some unknown planet. A few years afterwards this explanation received some support from the circumstance that the observations of the planet made subsequent to the year 1821, began to exhibit a deviation from Bouvard's tables. This deviation continued to increase, until at length in the year 1830, the error in longitude amounted to as much as half a minute of space.

In the year 1834, Dr. Hussey, writing to Mr. Airy, announced that he found it impossible to reconcile his own recent observations of the planet with Bouvard's tables. Taking this fact in connection with the discordances which the French astronomer found to exist between the earlier and the more modern observations, he suggested whether the various errors might not be attributable to the action of some planet beyond Uranus, and he expressed his intention of sweeping for the undiscovered body with his large reflector, provided one or two positions of it were determined empirically. Similar suspicions of the existence of an exterior planet occasioning the anomalies in the movement of Uranus were entertained by M. Valz, Mrs. Somerville, Professor Mädler, and several others.

It would appear that Bessel, shortly before his death, had formed the resolution of determining the position of the undiscovered planet by an analytical investigation of the subject. On the occasion of a visit which he paid to England in 1842, he expressed to Sir John Herschel his firm conviction that the anomalies were due to the disturbing action of an exterior planet, and he stated that as soon as he had concluded certain researches in which he was engaged, he would seriously apply himself to the question of ascertaining its actual position. In accordance with this resolution he caused all the observations of the planet to be carefully reduced by M. Flemming, a young German astronomer, but he was soon afterwards seized with the illness of which he died, and no further progress was made in the inquiry.

The theory of Uranus was shortly afterwards taken up as a subject of analytical investigation by Mr. J. C. Adams, of St. John's College, Cambridge. He was first led to suspect that the errors in the tables of the planet were due to the disturbing action of some planet revolving beyond Uranus, by a perusal of Mr. Airy's account of the progress of astronomy published in the 'Report of the British Association,' for 1832. In his note-book he found the following memorandum inserted under the date of July 3, 1841. "Formed a design, in the beginning of this week, of investigating, as soon as possible after taking my degree, the irregularities in the motion of Uranus, which are yet unaccounted for; in order to find whether they may be attributed to the action of an undiscovered planet beyond it, and if possible, thence to determine approximately the elements of its orbit, &c., which would probably lead to its discovery."

Mr. Adams took his degree in January, 1843, and shortly afterwards proceeded to a consideration of the theory of Uranus. The determination of the position of the undiscovered planet by means of the outstanding errors in the motion of Uranus involves the solution of what is called the inverse problem of perturbation. It was necessary, in the outset of his researches, to make some assumption with respect to the distance of the undiscovered body. In accordance with Bode's law of the planetary distances, he supposed the distance of the exterior planet from the sun to be equal to twice the distance of Uranus from the sun. In the autumn of 1845 his researches were so far matured as to suggest the expediency of instituting a search for the undiscovered body. On one of the last days of October, 1845, he called at the Royal Observatory and left a paper containing the following elements of the planet, which he had ascertained by a course of rigorous investigation:

Mean distance from the Sun, the earth's distance being represented by unity	38.4
Mean sidereal motion in 365.25 days	1° 30' 9"
Mean longitude, October 1, 1845	323° 34'
Longitude of perihelion	315 55
Excentricity	0.1610
Mass (that of the Sun being unity)	0.0001656

These elements give 326° 37' for the true heliocentric longitude of the planet on October 1, 1845. The elements of the planet, derived

from observations made subsequently to its discovery, assign $324^{\circ} 48'$ as its longitude for the same day. The difference therefore between the theoretical and the actual places of the planet amounts to only $1^{\circ} 49'$. The errors in the longitude of Uranus were shown to be accounted for most satisfactorily by the disturbing action of the hypothetic planet.

"Thus it appears that as early as the month of October, 1845, seven months before any other person had arrived at a similar conclusion, Mr. Adams had solved the inverse problem of planetary perturbation; that by means of his solution he had discovered, theoretically, the existence of a planet exterior to Uranus; and that he had assigned to the unknown body a place in the heavens which was subsequently found to differ little more than one degree from its actual place. All that was now wanting therefore to assure, both to Mr. Adams and to his country, the undivided honour of one of the noblest discoveries recorded in the annals of science, was some zealous observer to give effect to his results by carefully searching the heavens in the vicinity of the place indicated by his theory as that occupied by the planet. If such a scrutiny had been undertaken, and prosecuted for some time, it would beyond all doubt have resulted in the actual discovery of the planet, and the name of Adams would have been alone associated with that remarkable triumph of science. Such a consummation was not destined to be the reward of Mr. Adams; but this circumstance does not detract in the slightest degree from the merits of his researches; for it is now universally admitted that he was the first theoretical discoverer of the planet, and that as far as the task of the mathematician was concerned he left no part of the problem relative to the determination of its actual position to be completed by others."*

Shortly after receiving Mr. Adams's communication respecting the trans-Uranian planet, Mr. Airy wrote to Mr. Adams requesting to know whether the errors in the radius vector of Uranus were accounted for by the action of the undiscovered planet as satisfactorily as the errors in longitude. He considered that the explanation of the errors of the radius vector would form an *experimentum crucis* for testing the validity of Mr. Adams's researches, and he has stated that if a satisfactory reply had been returned to his communication he would at once have taken steps to institute a search for the planet.† Mr. Adams inadvertently omitted to furnish Mr. Airy with the desired information. This is more especially to be regretted as it would not have cost him the slightest effort to have returned a satisfactory reply to the Astronomer Royal.

It is right to state that the remarkable researches of Mr. Adams were not hitherto published. In fact it does not appear that at this period any one was acquainted with his labours except a few of his friends at Cambridge and the Astronomer Royal.

Allusion has been made to the failure of Bouvard's attempt to construct tables of Uranus capable of representing all the observations of the planet. A similar attempt of his nephew, Eugene Bouvard, in 1845, was not attended with much greater success. It was probably this circumstance which induced the late M. Arago, in the same year, to propose to M. Le Verrier, as a subject of investigation, the irregularities in the motion of Uranus. M. Le Verrier was engaged at the time in researches on the movements of comets, but he did not hesitate to adopt the suggestion of M. Arago, and laying aside his cometary labours for a future occasion, he commenced a rigorous investigation of the theory of Uranus. On the 10th of November, 1845, he communicated to the Academy of Sciences of Paris an account of the first part of his researches. They consisted in a new determination of the elements of the planet and a careful investigation of the perturbations produced in its motion by all the known bodies of the planetary system which are capable of exercising a sensible influence. On the 1st of June, 1846, M. Le Verrier communicated to the Academy of Sciences an account of the second part of his researches on the theory of Uranus. Finding it impossible to account satisfactorily for all the observations of the planet by the existing theory, he was led to consider whether the outstanding discordances between theory and observation might not be due to the disturbing action of some planet revolving beyond Uranus, and the problem which now presented itself to him was to determine the whereabouts of the unknown body, corresponding to a given instant of time. The final result which he deduced at this stage of his labours was, that on the 1st of January, 1847, the true heliocentric longitude of the planet was 325° , and that the probable error did not exceed 10° .

The close accordance exhibited between the results arrived at by Mr. Adams and M. Le Verrier, independently of each other, afforded strong evidence in favour of the theory on which they were founded. Mr. Airy was consequently induced to suggest to Professor Challis, of Cambridge, the desirableness of instituting a search for the planet with the large telescope of the Observatory, known as the Northumberland refractor. Professor Challis adopted the views of the Astronomer Royal, and commenced a systematic search for the planet on the 29th of July.

On the 31st of August, 1846, M. Le Verrier communicated to the Academy of Sciences an account of the third part of his researches on

* Grant's 'History of Physical Astronomy,' p. 173.

† Mem. Ast. Soc., vol. xvi.

the theory of Uranus. The following are his final results in regard to the orbit of the unknown planet:—

Semi-axis of the orbit	36.154
Sidereal revolution	217.387 years.
Excentricity	0.10761
Longitude of the perihelion	$284^{\circ} 45'$
Mean longitude, January 1, 1847	$318^{\circ} 47'$
Mass	1
True heliocentric longitude, January 1, 1847	$326^{\circ} 32'$
Distance from the sun, January 1, 1847	33.06

On the 2nd of September, 1846, Mr. Adams communicated to the Astronomer Royal the final results of his researches on the disturbing planets. On this occasion he diminished the hypothetic value of the mean distance from 38 to 37.5. The following are the values of the other elements as deduced by him.

Mean longitude, October 1, 1846	$323^{\circ} 2'$
Longitude of the perihelion	$299^{\circ} 11'$
Excentricity	0.12062
Mass	0.00015003

On the 18th of September, 1846, M. le Verrier addressed a letter to Professor Encke, the Director of the Berlin Observatory, announcing to him the results of his researches on the trans-Uranian planet, and requesting him to institute a search for it in the region indicated by theory. This letter was received at Berlin on the 23rd of the month. On the same evening, Dr. Galle, Professor Encke's assistant, examined the regions of the heavens indicated by M. Le Verrier, as comprising the locus of the disturbing planet, with the assistance of the corresponding map of the Berlin Academy, which had just been engraved, and he found that a star of the eighth magnitude, situate very near the place assigned by M. Le Verrier to the disturbing planet, was not laid down on the map. An examination of the same region on the following evening established beyond doubt the interesting fact that the object thus observed was the planet. The following comparison will serve to show how nearly M. Le Verrier approximated in his researches to the actual position of the planet:

True heliocentric longitude, September 23, 1846	$326^{\circ} 57'$
Longitude assigned by the theory of M. Le Verrier	326°

Difference between observation and theory . . . $57'$

Professor Challis, who had commenced a systematic search for the planet, as early as the 29th of July, first received information of the discovery of the planet by Galle, on the 1st of October. He had already noted down the positions of 3150 stars comprised in the region which he proposed to explore. He now proceeded to discuss the results, in order to ascertain whether they included any places of the disturbing planet. It appeared from this examination that he had determined the position of the planet on the evening of August 4, and also on August 12, and it consequently followed that his plan of search, when carried into complete effect, would have infallibly led to the discovery of the planet. He also observed a star on the 29th of September, which seemed to have a disk, but unfortunately he did not establish the real nature of the object, which turned out afterwards to be the planet.

By the unanimous concurrence of astronomers, the new member of the planetary system has been called Neptune. It is plain from the brief account which we have given, that its theoretical discovery is due to the independent researches of Mr. Adams and M. Le Verrier. It is true that the optical discovery of the planet was effected solely by the aid of M. Le Verrier's indications, but it is equally true that the same object might have been achieved by means of Mr. Adams' theoretical results; and indeed we have seen that Professor Challis obtained two positions of the planet, solely by relying on the latter.

Soon after the discovery of the planet Neptune, it was found that it had been observed as a star by Lalande, on the 10th of May, 1795. This circumstance enabled astronomers to determine the orbit of the planet with a greater degree of precision than could otherwise have been expected until after the lapse of several years. The following elements of the orbit of the planet are due to the late Mr. Walker, of Washington, U. S.

Mean distance	30.0363
Mean longitude, January 1, 1847, M.T. Greenwich	$328^{\circ} 32' 44''.20$
Excentricity	0.00871946
Longitude of perihelion	$47^{\circ} 12' 6''.50$
Longitude of ascending node	$130^{\circ} 4' 20''.81$
Inclination	$1^{\circ} 46' 58''.97$
Mean daily motion	$21''.55448$
Periodic time	164.6181 trop. years.

These elements represent the observations of the planet with a remarkable degree of precision. It will be seen that they differ in several respects very considerably from the corresponding results obtained by Mr. Adams and M. Le Verrier. This circumstance presented a difficulty to the minds of several persons, who even went so far as to assert that the planet Neptune did not represent the theoretical planet indicated by the researches of those geometers, and that

its discovery was the result of a happy accident! But any such difficulty will vanish when it is borne in mind that the object proposed by M. Le Verrier and Mr. Adams was not to determine rigorously the elements of the disturbing planet, which could only result from the discussion of a series of its observed positions, but merely to ascertain its whereabouts during the period when its perturbations were sensible. For this purpose, any combination of elements varying within considerable limits will be sufficient. During the whole of the period comprised between the year 1690 and the beginning of the present century, the disturbing action of Neptune was incapable of exercising any appreciable influence on the motion of Uranus. During the present century, however, the perturbations have been of sensible magnitude. It was therefore necessary that throughout this period the intensity and direction of the disturbing force, and consequently the position of the disturbing body, should be represented with considerable precision by the theoretical results of M. Le Verrier and Mr. Adams. That this object was effected by both of the geometers just mentioned may be readily seen by the following numbers, which exhibit a comparison between the heliocentric longitude and radius vector of Neptune for every ten years since the year 1800, and the corresponding values of the co-ordinates, as deducible from the researches of M. Le Verrier and Mr. Adams:—

Year.	Planet Neptune.		Theory of Le Verrier.		Theory of Adams.			
					First Approximation.		Second Approximation.	
	Longi- tude.	Rad. vect.	Longi- tude.	Rad. vect.	Longi- tude.	Rad. vect.	Longi- tude.	Rad. vect.
1800	226° 4'	30.30	231° 34'	33.57	236° 46'	36.31	238° 9'	34.90
1810	247 20	30.28	251 10	32.80	254 13	34.75	256 39	33.92
1820	268 52	30.23	271 28	32.35	273 11	33.45	276 5	33.25
1830	290 31	30.55	292 8	32.29	293 27	32.56	295 54	32.96
1840	312 17	30.06	312 36	32.63	314 30	32.22	316 10	33.11
1850	334 12	29.96	332 25	33.32	335 36	32.48	325 50	33.67
1860	356 14	29.87	351 17	34.26	356 1	33.30	334 39	34.57

Shortly after the discovery of Neptune, Mr. Lassell discovered that it was attended by a satellite. M. Otto Struve found from his own observations, made with the great refractor of Pulkowa, that the semi-major axis of its apparent orbit is 17".89, and that it revolves round the planet in a period of 5^d 21^m 15^s. These elements give for the mass of the planet the value $\frac{1}{1464}$, the sun's mass being represented by unity. Professor Peirce, of Harvard College, Cambridge, U.S., determined the mass of the planet from observations of the satellite made by the late Mr. Bond, Director of the Cambridge Observatory, and found it to amount to $\frac{1}{10840}$, in terms of the same unit. Adopting this value of the mass, Professor Peirce calculated the perturbations produced by the planet in the motion of Uranus, and he obtained results which on the whole represent very satisfactorily the irregularities in the motion of the latter planet which so much perplexed astronomers previously to the discovery of Neptune. It will be seen that the mass of Neptune, as deduced from the observations of the satellite either by M. Otto Struve or Mr. Bond, is considerably less than the value of the same element assigned by Mr. Adams or M. Le Verrier. It is to be borne in mind, however, that, on the other hand, the researches of both these geometers make the distance of the planet from the sun greater than the true distance. A compensation is thus effected, so that the intensity of the disturbing force presents a satisfactory agreement in all three cases. How nearly the direction of the disturbing force agrees in so far as regards the real and the theoretical planets, has been shown by the table just given.

M. Kowalski has recently published tables of Neptune, which are used in the 'Nautical Almanac' for computing the ephemeris of the planet. Mr. Adams's researches on the theory of Uranus are to be found in the Supplement to the Nautical Almanac for 1851; those of M. Le Verrier on the same subject are published in the 'Connaissance des Temps' for 1849.

NEPTUNUS. [POSEIDON.]

NEREIDS (*Nηρηίδες*), nymphs of the sea, or rather of the Mediterranean, in contradistinction to the Naiades, who were the nymphs of fresh waters, and to the Oceanides, who were nymphs of the great ocean. The Nereids were the daughters of Nereus and Doris. Nereus was the eldest son of Pontus and the Earth (Hesiod, 'Theog.', 233); and Doris was one of the daughters of Oceanus. The Nereids are said by most ancient writers to have been fifty in number, but Propertius makes them a hundred (iii. 5, 33). The most celebrated of them were Amphitrite, the wife of Poseidon; Thetis, the mother of Achilles; Galatea, Doto, &c. (Homer, 'Iliad', xviii., 39–50, &c.)

The worship of the Nereids was generally connected, as might be supposed, with that of Poseidon. Thus they were worshipped in Corinth, where Poseidon was held in especial honour, and in other parts of Greece. They were the patrons of the Argonauts, and seafaring people generally. (Paus., ii. 1, § 7, 8; compare iii. 26, § 5; v. 19, § 2.) The Nereids are frequently represented on reliefs, gems, &c. They are usually represented as beautiful nymphs [NYMPHS], mostly half

draped, but sometimes unclothed. They are often figured sporting with Tritons; sometimes riding on sea-panthers, griffins, the hippocampus, and other sea monsters. They are also seen as they were described by later writers, as beings with green hair, and with the lower part of their body like that of a fish (Plin., 'Hist. Nat.' ix. 4.); unless those on Greek gems are rather to be regarded as female Tritons.

NESTORIANS. [NESTORIUS, in BIOG. DIV.]

NET and LACE. [WEAVING.]

NEURALGIA, a word of modern origin (derived from *νεῦρον*, a "nerve," and *ἄλγος*, "pain"), first employed by Chaussier to designate a certain class of diseases of which the characteristic symptom is a most acute pain following the course of a nerve in one or more of its ramifications, subject to paroxysms and intermissions, in most cases unattended by either heat, redness, or swelling, and often without any apparent lesion at all.

Although from the nature and causes of the affection we have every reason to believe that neuralgia must have existed in all ages, still (historically speaking) it may be called a modern disease, as the first distinct description of it that we possess is that published by André, a surgeon of Versailles, in 1756, in his 'Observ. Prat. sur les Maladies de l'Urèthre.' He, however, had only met with one species, namely, *Neuralgia Faciei*, which he called "tic douloureux,"* a name which, in popular language, it still retains; but since his time the same disease (subject only to certain local modifications) has been observed in various other parts of the body, and it is probable that every sensationary nerve is liable to the same morbid condition. Chaussier has enumerated nine species (of which the three first are merely varieties of the neuralgia faciei), namely: 1. *Neuralgia frontalis*, which is seated in the frontal division of the first or ophthalmic branch of the fifth pair of cerebral nerves. The pain begins at the supra-orbital foramen, and extends to the forehead, the upper eyelid, the eyebrow, the caruncula lachrymalis, the inner canthus of the eye, and sometimes to the whole of that side of the face. 2. *Neuralgia sub-orbitalis*, which occupies the superior maxillary nerve, or second division of the fifth pair. The pain begins at the infra-orbital foramen, and extends to the cheek, the upper lip, the ala nasi, the lower eyelid, and the teeth of the upper jaw. 3. *Neuralgia maxillaris*, which is seated in the inferior maxillary nerve, or third division of the fifth pair. The pain commences at the mental foramen, and either extends to the chin and lip, or else to the teeth of the lower jaw, the tongue, and the temple. 4. *Neuralgia Ilio-scrotalis*, which occupies the ilio-scrotal nerve, or external division of the musculo-cutaneous branches given off by the lumbar plexus, and derived from the first lumbar nerve. The pain commences at the crista ilii, follows the spermatic cord, and extends to the scrotum and the testicle. 5. *Neuralgia femoro-poplitealis*, which is seated in the great sciatic nerve. The pain begins over the sacrum, or about the great trochanter, follows the course of the nerve down the posterior part of the thigh to the popliteal space, and thence extends along the peroneal nerve, or external division of the great sciatic, to the outside of the foot. 6. *Neuralgia femoro-prætibialis*, which occupies the crural nerve, given off by the lumbar plexus, and derived from the second, third, and fourth lumbar nerves. The pain commences at the crural arch, extends along the anterior and internal part of the thigh, and sometimes follows the course of the internal saphenous nerve, one of the deep-seated branches of the crural, to the inner ankle and the dorsum of the foot. 7. *Neuralgia plantaris*, which is seated in the external and internal plantar branches of the posterior tibial nerve, or internal division of the great sciatic. The pain begins at the heel, shoots across the sole of the foot, and extends sometimes up the calf of the leg towards the knee. 8. *Neuralgia cubito-digitalis*, which occupies the ulnar nerve, given off by the brachial plexus, and derived from the fifth, sixth, seventh, and eighth cervical nerves. The pain sometimes commences at the upper part of the arm, and follows the course of the nerve along the ulnar border of the fore-arm to its termination in the inside of the middle, the ring, and the little fingers; sometimes only part of the nerve is affected, and the pain is confined to the humerus, or commences at the elbow. 9. "*Névralgies Anomales*: douleurs ordinairement chroniques, dont le siège varie à l'infini." Several of these have been particularly described, and constitute so many additional distinct species:—1. *Otalgia* (described by M. Itard), which is seated in the corda tympani, a portion of the vidian nerve, or posterior branch of Meckel's ganglion; and which is characterised by an acute pain following the course of this nerve. 2. *Neuralgia cervicalis* is of rare occurrence: M. Bosquillon has observed two cases after opening the external jugular vein, in consequence of wounding the superficial branches of the cervical plexus formed by the anterior branches of the second, third, and fourth cervical nerves; and M. Jolly

* The meaning of the term *Tic Douloureux* appears to be rather doubtful. In the 'Dictionnaire de Trévoux,' the word *Tic* is said to mean, first, a vicious trick that horses have of biting the manger; and secondly, "a sort of convulsive movement to which some persons are subject." These twitchings not being accompanied with pain, the epithet "douloureux" was added to distinguish those in neuralgia from every other sort. Dr. Good, however, considers the word *tic* to be "an onomatopoeia, or sound expressive of the action it imparts." The "*Tic Douloureux*" is called "*Dolar crucians Faciei*," by Fothergill; "*Trismus Maxillaris*," and "*Trismus Dolorificus*," by Sauvages; "*Proso-palgia*," by Swediaur; "*Neuralgia Faciei*," by Good; "*Autalgia Dolorosa*," by Young.

has met with another after the application of leeches to the side of the neck. 3. *Neuralgia intercostalis* (first described by Siebold, and afterwards by Corvisart) occupies either a portion or the whole of one of the intercostal nerves, generally in the lower part of the thorax. 4. *Neuralgia cervico-brachialis* (first noticed by Professor Fulci of Catania), is seated in the internal cutaneous nerve, a branch furnished by the brachial plexus. The pain begins at the anterior and internal part of the shoulder, and descends along the inner side of the arm and fore-arm to the wrist. Sometimes it extends not only to all the branches of the internal cutaneous nerve, but also to those of the external, and then becomes confounded with the following species. 5. *Neuralgia musculo-cutanealis* was first described by M. Martinet, and occupies the external cutaneous (or *musculo-cutaneous*) nerve, another branch derived from the brachial plexus. The pain commences at the shoulder, descends along the anterior external surface of the arm and fore-arm as far as the wrist. 6. *Neuralgia supra-scapularis* was also first described by M. Martinet, and is seated in the suprascapular nerve, another branch given off from the brachial plexus. The pain begins at the inferior angle of the scapula, passes along its posterior surface, and sometimes descends along the radial border of the fore-arm to the thumb and fore-finger. 7. *Neuralgia mammae*, first described by Dr. Good as consisting of "sharp, lancinating pains, divaricating from a fixed point in the breast, and shooting equally down the course of the ribs and of the arm to the elbow; the breast retaining its natural size, complexion, and softness." 8, and last, *Neuralgia of the facial nerve, or portio dura of the seventh pair*, about the existence of which there is great room for doubt; for as this is a nerve of *motion* and not of *sensation*, it is not easy to understand how it should be liable to be affected by a disease which is in general simply and purely painful. However, it is still more difficult to deny the fact; numerous instances have occurred in which the disease has (to all appearance) been seated in this nerve, and several wherein the pain has not only followed its ramifications with great exactness, but has also been attended by convulsive twitchings of the facial muscles, and even by their paralysis.

But besides these external forms of neuralgia, the disease has sometimes been found to attack various internal organs. This was first suggested by Dr. John Fothergill in 1773, who says (in Vol. v. of the 'Med. Observ. and Enquiries,') "There are few physicians, I believe, who may not in reviewing many cases, which have occurred to them, of anomalous pains in different parts of the body, so as sometimes to counterfeit gouty, bilious, and other internal affections of the stomach and bowels, perceive some analogy between them and the complaint here pointed out;" but it is only lately that pathologists have begun to enumerate these "anomalous pains," and class them as so many distinct species of neuralgia. Sometimes the central mass of the nervous system is affected, and we find the terms "Cerebralgia" and "Myelalgia" employed by some modern French authors to designate neuralgia of the brain and of the spinal chord. (Raciborski, 'Précis du Diagnostic,' 1837.) Sometimes, instead of the branches of a nerve, the extreme filaments only are diseased, as would appear to be the case in many of those kinds of pain commonly called "rheumatic" (MM. Jolly and Piorry, quoted in Raciborski). To these have been added torticollis, lumbago, angina pectoris, neuralgia of the arteries, gastralgia, enteralgia, hepatalgia, nephralgia, hysteralgia, neuralgia of the heart, testicle, bladder, urethra, diaphragm, &c. (Raciborski, Rowland, Elliotson, &c.) It may perhaps be rather fanciful to give the name "neuralgia" to all these cases, and it would take up too much space to describe each separately; but they are all characterised by an increased sensibility of the nerve, and have the same general character of coming on in paroxysms at regular or irregular intervals.

Of the remote or predisposing causes of neuralgia very little is known, but it has been supposed to attack females more frequently than males, the rich than the poor, those that live in towns rather than the inhabitants of the country. It is also most common among persons of a nervous temperament, and both infancy and old age are comparatively safe from its attacks. The immediate or exciting causes are very numerous, and sometimes extremely obscure. Among the most common may be mentioned, exposure to wet and cold, mental excitement and agitation in persons of an irritable temperament, and a deranged state of the digestive organs. Local injuries of various kinds are another very frequent cause of the disease; such as the lodgment of any foreign body in the branch of a nerve, wounds, contusions, cicatrices, the too great distension of a nerve, carious teeth, &c. Sir Henry Hallford has published in his 'Essays,' five cases showing that sometimes "the disease is connected with some preternatural growth of bone, or a deposition of bone in a part of the animal economy where it is not usually found in a sound and healthy condition of it, or with a diseased bone;" and Sir Benjamin Brodie, in his 'Lectures on Local Nervous Affections,' mentions several where the pain was occasioned by the pressure of an aneurysmal or other tumour. Another cause is exposure to malarious poison. This is more especially the case in those attacks which are regularly intermittent, and which yield to the same treatment as ague. Puerperal women are also subject to this disease, especially after large floodings during labour.

With regard to the seat of neuralgia, there can be little doubt but that it is in the nerve itself; but it is equally certain that the part where pain is felt is not always the part diseased. The fact is, neu-

ralgia of any nerve may be purely the result of irritation reflected from a very distant point of the nervous system. Post-mortem examination throws no light on the state of the nerve, but there is no reason to believe that it arises from an inflamed or congested state of the nerve in which the pain has been experienced.

The diagnosis of neuralgia is not in general very difficult, for even when it does not follow the course of a nerve, it may commonly be distinguished from every other disease by the peculiar character of the pain, its excessive violence during the paroxysm, and the absence of all symptoms of fever and inflammation. It may sometimes be difficult at first sight to distinguish neuralgia from rheumatism, inasmuch as the two diseases resemble each other in some of their most prominent symptoms; but by observing the following diagnostic signs (derived from the general character of inflammation in all parts of the body), the danger of confounding them may be avoided. In rheumatism the pain is continual, as is the case in all inflammations: in neuralgia it is never constant, but is subject to paroxysms and intermissions. In rheumatism the pain is aggravated by the slightest pressure; in neuralgia, on the contrary, it is sometimes alleviated by it. To these it may be added that in rheumatism we shall find the usual attendants of inflammation, namely, heat, redness, and swelling; while in neuralgia (as noticed above) these are rarely if ever present.

Dr. Inman has recently pointed out that a painful condition of the muscles, ordinarily known by the name of cramp, is frequently mistaken for neuralgia. This disease, which he calls myalgia, he says may be recognised: 1. By the pain being hot and burning; 2. By its absence in the morning, and increase during the exertion of the day; 3. By its seat in some one muscle, and being increased by the movement of that muscle; 4. It is the result of unusual exertion of the muscle; 5. It is relieved by relaxation, or artificial support; 6. The pulse is unaffected; 7. The pain of cramp often comes on suddenly during the night. The distinction between myalgia and neuralgia is of importance, as the treatment of the two diseases might be directly opposite.

With regard to the treatment of neuralgia, it would appear quite superfluous to say that it must be regulated by the circumstances of each particular case, if it were not notorious that no disease has been treated more blindly and empirically. When any foreign body presses upon the nerve, or when the pain can be distinctly traced to a carious tooth, the removal of the source of irritation will commonly be sufficient to cure the disease, though the practitioner should be especially warned against the danger of confounding neuralgia with the tooth-ache—an error that is not unlikely to occur in some cases of tic douloureux, and one that has often occasioned the loss of several teeth to the patient without any good effect. When (as is sometimes the case) the disease appears to be occasioned by the irritation arising from an old cicatrix, it will be expedient to try the effect of applications to the cicatrix itself—namely, either the nitrate of silver, or the actual cautery, or a blister, or a crucial incision over the part, or even its removal by the knife. And in the same way, when it can be distinctly referred to any other of the exciting causes enumerated above, the removal of that will probably be followed by the disappearance of the disease. But, as already observed, it very frequently happens that the exciting cause cannot be discovered, and in these cases the treatment must necessarily be in a great degree empirical. When the paroxysms are irregular in their duration and recurrence, perhaps the sesquioxide of iron is the best remedy at present known: it may be given in doses of half a drachm three times a day in twice its weight of treacle. When the pain recurs after certain regular intervals, those medicines which are found to be most efficacious in the treatment of ague may be exhibited with advantage. The disulphate of quina may be given in doses of four or five grains three times a day, though this medicine has sometimes been given in much larger quantities, and Sir Benjamin Brodie mentions one case where the patient took as much as half a drachm daily. ('Local Nervous Affections,' p. 28.) The liquor potassæ arsenitis is another excellent medicine which may be employed in this form of disease: the dose is at the commencement four or five minims three times a day, which may gradually and cautiously be increased to ten or fifteen. When there are any signs of inflammation present, that the disease may seem rather to deserve the name of neuritis than of neuralgia, it must be treated accordingly, and the usual antiphlogistic remedies, both external and internal, may be employed. In almost every case of neuralgia it will be advisable to exhibit some preparation of opium, both to relieve the pain and also in order to procure the patient some sleep at night, at which time the paroxysms are often much aggravated; and especial care must also be taken not only to prevent the constipation caused by this drug, but also to keep up a free evacuation of the bowels, as in some cases the disease appears to have been cured by purgative medicines alone.

Among local applications may be mentioned the unguentum veratri, emplastrum opii, and empl. belladonnæ, or a lotion (recommended by Dr. Bennett, of Charleston in America), composed of four ounces of the aqua laurocerasi and one ounce of sulphuric ether, either alone or with half or one drachm of the extract of belladonna. The application of an ointment with one or two grains of aconitina to a drachm of lard has also been strongly recommended. Counter-irritants have often proved very efficacious, particularly the application of a common

blister, and, after the cuticle has been removed, the sprinkling over the denuded surface a quarter or half a grain of the acetate or hydrochlorate of morphia. Moxas and issues have also been tried with success. [ISSUE; MOXA.]

After all other remedies, both internal and external, have failed, the patient's last resource is the operation either of dividing the nerve or removing the limb; and even this will very often fail also. When the disease depends on some local irritation, or resides in the extremity of the nerve, the operation is frequently successful; but when it proceeds from constitutional causes, or exists either in the brain itself or nearer to it than the point where the nerve can be divided, in this case it is manifest that, as no benefit can reasonably be expected from the operation, the experiment ought never to be tried but at the earnest request of the patient. Sometimes the nerve is simply divided; but in these cases the pain very often returns as soon as the two extremities are re-united. Sometimes a portion of the nerve is removed; but even this appears only to obtain for the patient rather a longer respite. Latterly, after part of the nerve has been cut away, the two ends have been touched either with nitrate of silver or the actual cautery, and in some instances this plan appears to have succeeded where the simple section of the nerve had failed.

NEURITIS. [NEURALGIA.]

NEUTER. [GENDER.]

NEUTRAL AXIS. The neutral axis of a loaded body is an imaginary line, separating those portions of the body which are exposed to the action of opposite forces; as for instance, in the cases of girders, or occasionally of columns, there are some laminae which are exposed to compression, and others which are exposed to become extended, whilst there are laminae about which those forces of compression and extension are balanced in such a manner as to leave them in a neutral state, so long as the conditions of elasticity of the affected portions are not permanently injured. It had long been known, and has recently been proved by the investigations of Mr. E. Hodgkinson, that every body, or substance, used in the mechanical operations of building, or of machinery, has its own peculiar laws of elasticity; and it therefore follows that the position of the neutral axis in any of them must vary in an almost endless variety of manners, according to the shape of the particular body experimented upon, or to its physical properties. Thus wood has been ascertained to resist efforts of compression in nearly the same manner that it resists efforts of extension; whereas, cast iron resists the former class of efforts with a far greater degree of energy than it does the latter class; and wrought iron, again, is known to compress under smaller efforts than are required to extend it. Under these circumstances, the position of the neutral axis would vary in beams of either of those materials, if the same form of section be employed; or, in case it should be required to cause the neutral axis to pass through the same points, it would be necessary to change the form of the body, so as to bring into play the peculiar elastic properties it may possess in such a manner as to allow the sum of the resistances to contraction and expansion to balance one another on either side of the line of the immovable fibres. In rectangular beams of materials of an equal degree of elasticity under any description of effort, that is to say, under efforts either of compression or of extension, the neutral axis will be found to pass through the centre of gravity of the loaded beam; and in all cases the ratio of the moments of the material undergoing compression and extension about the neutral axis must be made equal to the ratio of the forces of extension and compression to secure stability. [RESISTANCE.]

NEUTRAL SALTS. [SALTS.]

NEUTRALISATION. In chemistry the operation of adding an acid to an alkaline solution, or vice versa, an alkali to an acid liquid, until the latter neither reddens blue litmus paper nor browns turmeric paper. Such a liquid is then said to be *neutral* or to possess a *neutral re-action*.

NEUTRIA. [FURRIERY.]

NEW TESTAMENT. [TESTAMENT, OLD AND NEW.]

NEW-YEAR'S-DAY. Of the customs formerly practised at the opening of the new-year, none appear to have been so universal as feasting and sending presents, both of which the moderns appear to have derived from the Romans. Suetonius ('August.' § 57, edit. varior., 8vo, 1647) alludes to the practice among the Romans of bringing presents to the Capitol on new-year's-day, whether the emperor was present or absent; and Tacitus speaks of an order of Tiberius, forbidding the giving or demanding of new-year's-gifts unless it were on the calends of January. The early fathers of the church condemned this practice as superstitious, because the gifts were considered as omens of success for the ensuing year.

New-year's-day with us, like many others, in modern times, has lost much of the ceremonials of its observance. In a volume of 'Miscellanies,' printed in Queen Anne's time, we read,—“January. On the

first day of this month will be given many more gifts than will be kindly received or gratefully rewarded. Children, to their inexpressible joy, will be drest up in their best bibs and aprons, and may be seen handed along streets, some bearing Kentish pippins, others oranges stuck with cloves, in order to gain a blessing of their god-fathers and godmothers.”

Gifts at new-year's-tide formed a charge of no small amount in the privy-purse expenses of royalty, from very early times to the time of Charles II.; they were mostly made in plate.

Moresin, who published his 'Papatus' in the time of James I., tells that in Scotland it was then the custom to send new-year's-gifts on new-year's-eve; and on new-year's-day they wished each other a happy day, and asked a new-year's-gift. When Brand wrote his 'Popular Antiquities,' it was still usual in Northumberland for persons to ask for a new-year's-gift on that day. The practice of "first-footing," in Scotland, is now dying out before the advance of temperance and education.

In France the custom of giving new-year's-gifts is still kept up, to such an extent as to make a vast addition to the business of the great towns in the articles usually selected for presents.

The modern Jews, on the first day of the month Tisri, which may be considered as their new-year's-day, usually have a splendid entertainment, and wish each other a happy new year.

Hospinian says, that at Rome on new-year's-day (he speaks of modern practices) no one would suffer a neighbour to take fire out of his house, or anything of iron, or lend anything. (Brand's 'Popular Antiq.')

New-year's-eve was celebrated by hospitality and drinking, seeing the old year out and the new-year in; the church bells were rung as the clock struck twelve. But these customs are disappearing like the others, although as yet the bell ringing is by no means uncommon. A midnight mass is now, we believe, held in most Roman Catholic places of worship in England; and a midnight service in many churches of the Establishment. Religious services, termed a "watch night," are also commonly conducted on New Year's eve, closing at a few minutes past twelve, in Wesleyan Methodist chapels, and by many Dissenters.

NEWSPAPERS. Some persons are of opinion that the origin of newspapers may be traced to the 'Acta Diurna' of the Romans. [ACTA DIURNA.] However this may be, it was not till the 16th century that anything at all approaching to the nature of the 'Acta Diurna' existed in modern times. The war which the republic of Venice waged against the Turks in Dalmatia gave rise, in 1563, to the custom in Venice of communicating military and commercial news by written sheets, which were read in a particular place to those desirous to hear them, and who paid for this privilege in a coin no longer in use, called *gazzetta*, a name which, by degrees, was transferred to the newspaper itself in Italy and France, and passed over into England. The Venetian government eventually gave these announcements in a regular manner once a month; but they were too jealous to allow them to be printed. Only a few written copies were transmitted to various places, and read to those who paid to hear. Many volumes of these manuscript newspapers exist in the Magliabecchian library at Florence.

For some time it was supposed that English newspapers were first established in the reign of Elizabeth, founded on the existence of three papers, numbered 50, 51, and 54, preserved in Dr. Birch's 'Historical Collections' in the British Museum, and imagined to belong to a series. But they were suspected not to be genuine. The suspicion was well founded. In 1839 Mr. Thomas Watts, one of the librarians of the British Museum, published a 'Letter to Antonio Panizzi, Esq.,' in which he proved incontrovertibly that they were forgeries, and that the forgery was perpetrated about 1766. The three numbers, which are marked as 50, 51, and 54, purporting them to be part of a series, contain seven articles, three of which are in print and four in manuscript. The type is of the date of 1766, but an old style of spelling is affected, while in the manuscript the spelling is modern, with a number of corrections in a different hand-writing; and the manuscript is written on a paper with the water-mark of the royal arms and initials of "G. R." In 1850 Mr. Watts made public the result of his further investigations, which showed that the manuscript was in the hand-writing of Philip Yorke, the second earl of Hardwicke, and a few of the corrections in that of Dr. Birch. Mr. Watts also proved that the claims of France for the earliest newspaper, the 'Gazette of Paris,' in 1631, are also unfounded, and that the earliest specimen of this branch of literature belongs "to Italy or to Germany." The claim of Germany is strongest: at Augsburg and Vienna printed sheets containing news were published as early as 1524.

In the reign of James I., packets of news were published in the shape of small quarto pamphlets occasionally. The earliest we have met with, preserved in the second volume of the series of newspapers purchased with Dr. Burney's library (also in the British Museum), is entitled 'News out of Holland,' published in 1619 for N. Newbery, followed by other papers of news from different countries in 1620, 1621, and 1622. There can be no doubt of the genuineness of these. In 1622, when the Thirty Years' War and the exploits of Gustavus Adolphus excited curiosity, these occasional pamphlets were converted into a regular weekly publication, entitled 'The News of the Present

Week,' edited by Nathaniel Butler. This seems to have been the first weekly newspaper in England.*

About this period newspapers began also to be established on the Continent. Their originator at Paris is said to have been one Renaudot, a physician, who had found that it was conducive to success in his profession to be able to tell his patients the news. Seasons were not always sickly, but his taste for collecting news was always the same, and he began to think that there might be some advantage in printing his intelligence periodically. His scheme succeeded, and he obtained a privilege for publishing news in 1632. It would appear that not long after this time there were more newspapers than one in England.

Upon the breaking out of the civil war in Charles I.'s time, great numbers of newspapers, which had hitherto been chiefly confined to foreign intelligence, were spread abroad by the different parties into which the state was then divided, under the titles of 'Diurnals,' 'Special Passages,' 'Intelligencers,' 'Mercuries,' &c., mostly in the size of small quarto, and treating of domestic matters. Nearly a score are said to have come out in 1643, when the war was at its height. Heylin, in the address prefixed to his 'Cosmographie,' enjoins the reader not to think himself unsatisfied in his expectation, if he find not in it "the situation and affairs of each town of war or the quartering-place of every company or troop of soldiers, which are presented to him in the weekly news-books." Hence we find some papers entitled 'News from Hull,' 'News from the North,' 'The last-printed News from Chichester, Windsor, Winchester, Chester,' &c., and others too numerous to mention. We also find 'The Scots Dove' opposed to 'The Parliament Kite,' or 'The Secret Owl.' Keener animosities, as Disraeli remarks, produced keener titles: 'Heraclitus Ridens' was met by 'Democritus Ridens,' and 'The Weekly Discoverer' was shortly met by 'The Discoverer Stript Naked.' 'Mercurius Britannicus' was grappled by 'Mercurius Mastix faithfully lashing all Scouts, Mercuries, Posts, Spies, and others.' Mercurius was the favourite name, with another word to indicate the character of the party from whom it emanated. Whenever any title however grew popular, it was stolen by the antagonist, who thus conveyed his opinions to those who would not have received them had he not worn the appearance of a friend.

Disraeli, in his 'Curiosities of Literature,' gives an account of the two principal persons who were at this time concerned in the newspaper press, Marchant Needham and Sir John Birkenhout. "Marchant Needham," he says, "the great patriarch of newspaper writers, was a man of versatile talents and more versatile politics, a bold adventurer, and most successful because the most profligate of his tribe. From college he came to London; was an usher in Merchant Taylors' School; then an under-clerk in Gray's Inn; at length studied physic and practised chemistry; and finally he was a captain, and, in the words of honest Antony à Wood, 'siding with the rout and scum of the people, he made them weekly sport by railing at all that was noble in his intelligence, called Mercurius Britannicus, wherein his endeavours were to sacrifice the fame of some lord, or any person of quality, and of the king himself, to the beast with many heads.' He soon became popular, and was known under the name of Captain Needham of Gray's Inn; and whatever he now wrote was deemed oracular. But whether from a slight imprisonment for aspersing Charles I., or some pique with his own party, he requested an audience on his knees with the king, reconciled himself to his majesty, and showed himself a violent royalist in his 'Mercurius Pragmaticus,' and galled the Presbyterians with his wit and quips. Some time after, when the popular party prevailed, he was still further enlightened, and was got over by President Bradshaw as easily as by Charles I. Our Mercurial writer became once more a virulent Presbyterian, and lashed the Royalists outrageously in his 'Mercurius Politicus.' At length, on the return of Charles II., being now conscious, says our friend Antony, that he might be in danger of the halter, once more he is said to have fled into Holland, waiting for an act of oblivion. For money given to a hungry courtier, Needham obtained his pardon under the great seal. He latterly practised as a physician among his party, but lived universally hated by the Royalists, and now only committed harmless treasons with the College of Physicians, on whom he poured all that gall and vinegar which the government had suppressed from flowing through its natural channel." In buffoonery, keenness, and boldness, Sir John Birkenhout, the other principal news-writer of the day, was not inferior, nor was he at times less an adventurer, than Needham. His 'Mercurius Aulicus' was devoted to the court, then at Oxford. Beside newspapers, he was the author of numerous small political pamphlets abounding in wit and satire.

In 1662 the 'Kingdom's Intelligencer' was commenced in London, which contained a greater variety of useful information than any of its predecessors. It had a sort of obituary, notices of proceedings in parliament and in the law courts, &c. Some curious advertisements also appear in its columns. In 1663 another paper, called 'The

Intelligencer, published for the satisfaction and information of the people,' was started by Roger (afterwards Sir Roger) L'Estrange, who warmly espoused the cause of the crown on all occasions, and infused into his newspapers more information, more entertainment, and more advertisements of importance than were contained in any succeeding paper whatever previous to the reign of Anne. L'Estrange continued his journal for two years, but dropped it upon the appearance of the 'London Gazette,' first called the 'Oxford Gazette,' owing to the earlier numbers being issued at Oxford, where the court was then holding and the parliament sitting, on account of the plague being in London. The first number of what has still continued to the present time as the 'London Gazette' was published at Oxford, February 4th, 1665. So numerous did these little *books of news*, as they were called, become at this time, that between the years 1661 and 1668 no less than seventy of them were published under various titles.

On the 12th of May, 1680, L'Estrange, who had then started a second paper, called the 'Observator,' first exercised his authority as licenser of the press, by procuring to be issued a "proclamation for suppressing the printing and publishing unlicensed news-books and pamphlets of news, because it has become a common practice for evil-disposed persons to vend to his majesty's people all the idle and malicious reports that they could collect or invent, contrary to law; the continuance whereof would in a short time endanger the peace of the kingdom; the same manifestly tending thereto, as has been declared by all his majesty's subjects unanimously." The charge for inserting advertisements (then untaxed) at this period, we learn from the 'Jockey's Intelligencer,' 1683, to be "a shilling for a horse or coach, for notification, and sixpence for renewing;" also in the 'Observator Reformed,' it is announced that advertisements of eight lines are inserted for one shilling; and Morphew's 'Country Gentleman's Courant,' two years afterwards, says, that "seeing promotion of trade is a matter that ought to be encouraged, the price of advertisements is advanced to two pence per line." The publishers at this time, however, were sometimes puzzled for news to fill their sheets, small as they were; but a few of them got over the difficulty in a sufficiently ingenious manner. The 'Flying Post,' in 1695, announces, that "if any gentleman has a mind to oblige his country friend or correspondent with this account of public affairs, he may have it for two-pence of J. Salisbury, at the Rising Sun in Cornhill, on a sheet of fine paper, half of which being blank, he may thereon write his own private business, or the material news of the day." Again, 'Dawker's News-Letter': "This Letter will be done upon good writing-paper, and blank space left, that any gentleman may write his own private business. It will be useful to improve the younger sort in writing a curious hand." Another publisher had recourse to an expedient for filling his sheet, curious enough: wherever there was a dearth of news, he filled up the blank part with a sufficient proportion from the Bible.

It was not until the reign of Anne that the Londoners enjoyed the luxury of a newspaper every day. The first was issued in 1709, and called 'The Daily Courant,' being published every day but Sunday. There were at this time seventeen others published thrice a week, and one twice. Among them was the 'British Apollo,' the 'General Postscript,' the 'London Gazette,' the 'Postman,' the 'Evening Post,' and the 'City Intelligencer.'

It was about this time that a new species of publication came out, which, although it would scarcely be regarded as belonging to the family of newspapers now, was held to be so then; and, in fact, for a considerable time after it was commenced, it included articles of news along with its other matter. We allude to those admirable publications, the 'Tatler,' 'Spectator,' 'Guardian,' &c., which formed the models of so many subsequent publications of the same kind. The first number of the 'Tatler' was published on the 23rd of April, new style, 1709; the last on the 2nd of January, 1711. Much space was occupied in each by advertisements, and the price of each number was a penny. The publication of the 'Spectator' began March 1, 1711, at the same price; but upon the imposition of the half-penny stamp-duty, which began August 1, 1712, the price was raised to two-pence. The halfpenny tax is conjectured to have been the cause of the 'Spectator' being stopped in the beginning of 1713. It was however immediately followed by the 'Guardian,' the first number of which appeared on March 2nd, 1713. This paper soon dropped, and was succeeded by the 'Englishman' in October the same year (professedly political). The 'Englishman' lasted for two years, and was in its turn supplanted by the 'Freeholder,' on December 23rd, 1715, the latter work being almost the sole production of Addison.

It may be sufficient to notice in few words two or three of the more remarkable journals only which have since succeeded. The 'Public Advertiser' was first printed under the title of the 'London Daily Post and General Advertiser,' so far back as 1726, and assumed its later name only in 1752. This paper was the vehicle through which 'Junius's Letters' were given to the world. The 'St. James's Chronicle' is another of our oldest papers; at its first publication it was an amalgamation of two papers (the 'St. James's Post' and the 'St. James's Evening Post'), both of which began in 1715. The 'North Briton,' edited by Wilkes, first appeared in 1762; and in the same year the 'Englishman' was established. The 'Englishman' attracted much notice about 1766, on account of the insertion of

* Before the introduction of printed newspapers, it appears that great families had a sort of gazettiers in London, who transmitted to them the news of the day in written letters. This custom accounts for the following memorandum preserved in the Clifford family: "To Captain Robinson, by my lord's commands, for writing letters of news to his lordship for half a year, five pounds." (Whitaker's 'Hist. of Craven.')

several satirical articles in it by Burke. The 'Times' was established January 1, 1788.

The following account of the origin of the newspaper stamp is given by Cooke, in his 'Life of Bolingbroke':—"Queen Anne, in one of her messages to parliament, declared that, by seditious papers and factious rumours, designing men had been able to sink credit, and that the innocent had suffered; and she recommended the House to find a remedy equal to the mischief. In obedience to the queen's desire, and at the instance of her secretary, the parliament passed a bill, in 1712, imposing a stamp-duty upon pamphlets and publications. At its origin the amount of this stamp was a halfpenny; and it is curious to observe what an effect this trifling impost had upon the circulation of the most favourite papers. Many were entirely discontinued, and several of those which survived were generally united into one publication." The Act which imposed this duty is 10 Anne, c. xix. It is to this Act that Swift alludes in his *Journal to Stella*, under August 7, 1712:—"Do you know that all Grub Street is dead and gone last week?"

By the 6th and 7th Wm. IV. c. 76, the stamp-duty on newspapers, which had been gradually raised to fourpence (with a discount of 20 per cent.), was reduced to one penny (without any discount), a discount of 25 per cent. being allowed for Ireland. The quantity of letter-press on a sheet of paper bearing a stamp of one penny was limited to 1530 square inches on one side. Above 1530 square inches, the stamp was three-halfpence; above 2295 inches it was two-pence.

In 1836, when the stamp-duty was fourpence, the total number of stamps issued for the United Kingdom was 35,576,000.

In 1851 the total number of penny stamps issued was follows:—

	At 1d.	At ½d.
England and Wales	65,741,271	11,684,423
Scotland	7,643,045	241,264
Ireland	6,302,728	43,358
Total	79,687,044	11,969,045

The penny stamp shows the number of newspapers, as the halfpenny was additional on supplements.

From the 5th July, 1833, the duty on advertisements was reduced from 3s. 6d. to 1s. 6d. in Great Britain, and to 1s. in Ireland. The following statement of the total number of advertisements, and total amount received therefrom, will show the results of this reduction:—

Year.	England and Wales.		Ireland.		Scotland.	
	Advts.	Duty.	Advts.	Duty.	Advts.	Duty.
1832	No. 783,557	£. 137,122	No. 121,991	£. 15,248	No. 104,447	£. 18,278
1851	No. 1,767,281	£. 136,546	No. 236,128	£. 11,806	No. 249,141	£. 18,705

In Scotland the newspaper-press was first introduced during the civil wars in the 17th century. When a party of Cromwell's troops arrived at Leith in 1652, for the purpose of garrisoning the citadel, they brought a printer, named Christopher Higgins, to reprint a London diurnal, called 'Mercurius Politicus,' for their amusement and information. The first number was issued on the 26th October, 1653; and in November the following year, the establishment was transferred to Edinburgh, where this reprinting system was continued till the 11th April 1660. On the 31st December, 1660, appeared at Edinburgh the 'Mercurius Caledonius,' purporting to comprise "the affairs in agitation in Scotland, with a survey of foreign intelligence." It was a small quarto of eight pages. The last number was dated March 22 to March 28, 1661. It was succeeded by 'The Kingdom's Intelligencer.' In 1669 an 'Edinburgh Gazette' was published by authority, followed in 1705 by the 'Edinburgh Courant.' 'The Caledonian Mercury,' which still exists, was first published on April 28, 1720. After Edinburgh, the next place at which the publication of a newspaper was attempted in Scotland was Glasgow, where the first number of the 'Glasgow Courant' appeared November 11, 1715. 'The Glasgow Journal,' begun in 1729, still exists. An 'Aberdeen Journal, or North British Magazine,' began in 1746; the first number gave an account of the battle of Culloden; this paper still continues. The 'Dumfries Journal' was commenced in 1750; and others quickly followed. Scotland has several other country newspapers, the 'Elgin Courier,' the 'Banffshire Journal,' the 'Paisley Advertiser,' the 'Renfrewshire Independent,' &c. There are now twenty newspapers published in Edinburgh, of which four are issued daily; and twenty-two in Glasgow, of which four are daily papers.

In Ireland, as in England and Scotland, newspaper intelligence originated during civil commotion. As far back as 1641, at the breaking out of the Rebellion of that year, there was printed a news sheet called 'Warranted Tidings from Ireland;' but from that time to the beginning of the 18th century, we have no notice of any other print of the kind, although it is not improbable that there may have been some. About the year 1700, a newspaper called 'Pue's Occurrences,' named after the proprietor, was established in Dublin, and maintained itself for more than half a century. This was the first newspaper published in the Irish capital. The next Dublin print was 'Falkener's Journal,'

established in 1728: both were daily papers. Waterford appears to have followed Dublin in publishing news, by the establishment of a paper in 1729, entitled 'The Waterford Flying Post.' In November, 1766, the 'Waterford Journal' came out; and 'Ramsay's Waterford Chronicle' about the same time. The present 'Waterford Mirror' was started in 1801. The oldest existing newspaper in Ireland is the 'Belfast News Letter,' started in 1737. Among the other existing Dublin papers may be mentioned the 'Evening Post,' which has now existed about eighty years.

The abolition of the advertisement duty in 1853 (16 & 17 Vict. cap. 63); the total removal of the stamp duty in 1855, or at least rendering it optional for the purpose of paying the penny postage, which gives the privilege of circulating by post for fifteen days (18 & 19 Vict. cap. 25); and the introduction of machinery, by which from 10,000 to 15,000 copies can be produced perfect in an hour; have united in giving a marked impetus to the extension of newspapers in the United Kingdom. In London there are now (Aug. 1860) published 14 morning papers instead of 6. The 'Times,' which usually consists of 16 pages, or two sheets, each containing a printed mass of upwards of 19½ square feet, price 4d.; the 'Morning Advertiser,' the 'Morning Chronicle,' the 'Morning Herald,' the 'Morning Post,' and the 'Public Ledger,' each of 8 pages, and price 4d.; the 'Daily News,' price 3d., the 'Standard' and 'Daily Telegraph,' and the 'Morning Star,' each of 8 pages, published at 1d. each. The others are 'Lloyd's List,' the 'Commercial List,' and the 'Shipping Advertiser,' for commercial affairs, and 'L'Entr'act,' a penny paper devoted to theatricals. As there is now no record of the numbers printed, it is impossible to give more than approximations; but it is known that the 'Times' publishes daily from 50,000 to 60,000 copies; and the 'Standard' has asserted that on one occasion it printed 100,000, the general sale nearly approaching that number. It is clear, indeed, that only a very large sale, with numerous advertisements, for which the wide circulation renders them a good medium, can enable these low-priced newspapers to maintain themselves, particularly as some of them, the 'Standard' for example, do not rely on the higher-priced morning papers for the more expensive articles of intelligence, such as the foreign and telegraphic communications, reports in parliament, &c. Of evening papers there are now eight, the 'Globe,' the 'Evening Herald,' and the 'Sun,' price 4d., the 'Express,' and the 'Evening Journal,' are branches of the 'Daily News' and 'Morning Herald,' price 2d.; the 'Evening Star,' and the 'Evening Standard,' are in part second editions of the morning papers of the same names, and like them price 1d. The 'Shipping and Mercantile Gazette,' is a commercial paper, price 5d. The 'London Gazette' is published twice a week. The 'Evening Mail,' the 'St. James's Chronicle,' and the 'Record,' are published three times a week. Of weekly London papers there are altogether 139, but this includes literary papers, such as the 'Athenæum,' the 'Literary Gazette,' 'Punch,' 'Notes and Queries,' and many class publications, such as the 'Solicitor's Journal,' the 'Builder,' and the 'Pawnbroker's Gazette;' but they are all essentially newspapers, though not all political. One remarkable feature is the existence of a considerable number of local papers in London, the 'City Press,' the 'Clerkenwell News,' the 'Islington Gazette,' the 'Islington Times,' the 'Holborn Journal,' the 'St. Pancras and Holborn Times,' the 'Marylebone Mercury,' and several others. These are chiefly papers devoted to local affairs and advertisements, none of them exceeding a penny in price, and some being published at a halfpenny. Some of the other weekly papers are conducted with a large amount of literary and political talent, and are of a higher price, such as the 'Examiner,' the 'Spectator,' the 'Saturday Review,' the 'Press,' the 'Leader,' &c. Others appeal to cheapness and a variety of intelligence, and some of them reach a circulation of of nearly 200,000. Among those which reach a high number are some of the illustrated papers, such as the 'Illustrated London News,' the 'Illustrated Times,' &c. There are many other periodical publications, such as 'Household Words,' 'Chambers's Journal,' &c., which, as not containing news, are not included among newspapers. Of local newspapers published in England there are 559, and in Wales 25. Many of these are penny papers, which are mostly published in the smaller towns; but Birmingham has two daily papers and Liverpool one at that price. There are 15 newspapers published in Scotland, and the prices vary from a penny, of which price there are many and some of them daily, to fivepence; four of them are monthly agricultural papers; and two are daily issues of Edinburgh newspapers, which are published in a separate series twice a week. In Ireland there are 129 published, but only Belfast, Cork, and Dublin have any so low in price as a penny; and they are the only towns with a daily paper. In the Isle of Man and the Channel Islands, there are published 15 newspapers, at prices varying from a penny to threepence. In all the preceding statements we have named the price independent of the stamp, which in all cases is charged for extra if a stamped paper is required. As we have already mentioned, it is perfectly impossible even to guess at the total number printed, but in 1859 there were 70,500,000 passed through the post-office, of which about three-fourths bore the newspaper stamp, and the other fourth an affixed postage stamp. This number is less than in the two preceding years, no doubt from the increasing practice of sending newspapers by railway parcels instead of the post.

By the Act 18 & 19 Vict., cap. 27, any periodical publication, published at intervals, not exceeding thirty-one days, of which the print does not exceed the prescribed superficies, may claim to be stamped as a newspaper; but in such case the title must be printed on the top of every page, with the date of publication; and, when posted, must be folded so as to show the stamp denoting the duty. Newspapers to be sent abroad by post may be registered at the General Post-office, for which an annual fee of 5s. is charged, the year always terminating on the 30th of June. It is not absolutely necessary that the newspaper should be registered, but the English Post-office then charges 2d. in addition to the foreign or colonial postage. Before a newspaper can be published a notice must be given at the Inland Revenue Office, Somerset House, or at the District Stamp-office, where the form of a "declaration" will be given, in which is to be stated—the title of the intended paper, quoted literally; the place where it is to be printed, giving the number of the house, the name of the street and of the parish in which it is situated, and the name of the occupier if it forms part of a dwelling-house; and the like particulars respecting the place of publication if it differs from the place of printing; the Christian and surnames of the printers and publishers; the number of shares into which the property is divided whenever the number, exclusive of the printer and publisher, exceeds two; and the Christian and surnames, residences, and occupations, of every proprietor, with the number of shares belonging to each when exceeding two, exclusive of the printer and publisher. This declaration must be made by the proprietor, or two proprietors, or by two of the largest shareholders where the number exceeds two, who must also furnish two respectable householders as sureties against the publication of seditious, blasphemous, or personal libels, to the amount of 400*l.* in London and 300*l.* elsewhere. A newspaper published before these securities are given subjects the proprietors to a penalty of 20*l.* The paper when published must have across the bottom of the last page or the last column, the names and residences of the printer and publisher, the place of publication, the date, and the price, under a similar penalty for neglect. A supplement must not be issued without the paper itself; and a copy of the paper, which is paid for, must be transmitted to the Stamp-office on the day of publication or the day after in London, Edinburgh, or Dublin, and elsewhere within three days, under the like penalty of 20*l.* for each offence; but the penalties can only be sued for by the Attorney-General or the Stamp-office.

The size and amount of stamp-duty for newspapers are defined as follows by the 16 & 17 Vict., cap. 63:—Newspaper stamps are to be 1*d.* only, for a superficies of print, on one side of the paper, not exceeding 2295 inches, whether published as a supplement or not; any supplement that with the paper does not exceed that quantity is to be exempt; and any other supplement to a duly stamped newspaper not containing a superficies on one side of more than 1148 inches of print is to be subject to a stamp of one halfpenny; and any two supplements not containing more than 2296 inches, to a duty of one halfpenny each, provided each be published on one sheet of paper only. Newspapers not stamped go by post at the book-post rate of a penny for 4 ounces, twopence for 8 ounces, and then ascending by twopence for every fraction of 8 ounces; and any number may be sent in one envelope open at the ends.

The largest collection of newspapers in England is in the British Museum. This collection was commenced by a considerable number being sent there, at the time when the Museum was established, with the library of Sir Hans Sloane. Another collection, of itself valued at 1000*l.*, was purchased in 1813 with the library of the late Dr. Charles Burney. At the end of two or three years from the time of publication the commissioners of stamps now transfer to the British Museum, for public use, copies of all the stamped newspapers, both of town and country.

In Germany newspapers originated in the 'Relations,' as they were termed, which sprung up at Augsburg and Vienna in 1524, at Ratisbon in 1528, at Dillingen in 1569, and at Nürnberg in 1571, and which appeared in the form of letters printed, but without date, place, or number. The first German newspaper in numbered sheets was printed in 1612. Italian journals were also early, and France has many newspapers, both in Paris and the provinces, but they were started under the protection of the government, and have never been long free from government control. At present all are liable to warnings for any infraction of prescribed rules, involving suspension and ultimate suppression, a power that has been very freely exercised. Every civilised country has now its newspapers; and in the founding of an English or American settlement, the newspaper is among the first establishments.

In the United States the increase of newspapers has been more rapid than in England. In the year 1704, the first Anglo-American newspaper, called the 'Boston News Letter,' was published at Boston. In 1719 the first newspaper was published in Pennsylvania; and in 1733 the first newspapers were published in New York and Rhode Island. Now there is hardly a petty town in any of the twenty-six states without its newspaper, and in the large cities, such as New York, several are published daily. At the Census of 1850, as far as returns were made, there were 254 daily papers published in the United States; 115 "tri-weekly;" 31 "semi-weekly;" and 1902 weekly. Among these nearly 50 papers were published in the German language; about a

dozen in French; several in Spanish, Italian, &c. In Pennsylvania a considerable number of newspapers are printed in the German language, and distributed among the numerous German settlers in that state. One German newspaper at least is also published in Maryland, and perhaps more. In Louisiana, some papers are printed both in French and English.

NEWTON'S PRINCIPIA. [PRINCIPIA.]

NEXT OF KIN. [CONSANGUINITY; INTESTACY.]

NICE, COUNCIL OF. [COUNCIL, OF THE CHURCH.]

NICENE CREED, THE, is one of the three creeds received by the church of England. It consists of the creed drawn up by the first council of Nice, with the addition of that part which relates to the divinity of the Holy Ghost. It was adopted in its present shape at the second general council of Constantinople, A.D. 381.

NICHE (from the Italian *nicchia*, signifying also a nook), a small recess, or concavity in the face of a wall for the purpose of containing a statue. The Greeks rarely employed statues as external decorations to their edifices, sculpture being so applied by them only as friezes, or within pediments, and they did not therefore require niches. In Roman architecture, on the contrary, niches are of very frequent occurrence, and often enter very largely into a design as principal features in the composition. Niches are usually semicircular in plan, and round-headed, that is, covered by the quarter of a hollow sphere, owing to which the shadow within the concavity produces a beautiful curve. They are, however, occasionally made square in plan, in which case they are square-headed; but square-headed niches are sometimes made circular in plan, though round-headed ones are never square. Niches exhibit still greater diversity in the modes of decorating them; and they are sometimes left quite plain, and in this country, oftener than not, quite empty also; although a niche without a statue, vase, or some piece of sculpture in it, is a very questionable feature, suggesting to the spectator the absence of the object which it is intended to receive. When niches are decorated they are usually placed within a square-headed panel, having architraves and other dressings like those of windows, and therefore admit of as much variety of design as windows themselves. Many architects have given them columns, and thus converted them into small tabernacles (as in the upper order of the side elevations of St. Paul's), or have otherwise bestowed so much enrichment upon them that the statues within them are almost lost.

In Romanesque and Pointed Gothic architecture, niches are largely employed, and rendered a highly ornamental feature. In our own country we find them extensively used through every period, but varying in character in each. When employed in the Norman period they are mere shallow recesses, and but slightly ornamented. Sometimes they occur in a series under intersecting arches. In the First Pointed style they are more frequent, more deeply recessed, more ornamented, the sides have handsome mouldings, the heads have trefoil or cinquefoil cusps, and frequently they have a flat or projecting canopy. [CANOPY.] Sometimes the figures are set on low pedestals: good examples occur at Salisbury, Peterborough, and Wells Cathedrals, and of the transition to the Second Pointed period at Beverley Minster. In the Second Pointed, or Decorated style, still more regard is paid to the niches, which are now much more varied in character, and often highly elaborated. The top is frequently carved to imitate regular vaulting, the canopies are very various in form and decoration, but usually pedimental or ogee, projecting, and often ornamented with crockets, pinnacles, and a fully developed finial. Niches in this style often occur in buttresses, on the sides of doorways as at Rochester Cathedral, and on each side of the east window. The figures are usually placed on richly carved brackets. Good examples occur at Wells, Lichfield, Ely, and Rochester Cathedrals, and York and Beverley Minsters. In the Third Pointed, or Perpendicular style, niches are even more abundant, and in ornament more exuberant, the canopies often running upwards into small spires, and pinnacles, crockets, and finials being very profusely employed. The top is often groined, and has sculptured bosses. They may be seen in all important buildings of this style, but it will perhaps be enough to refer to Henry VII.'s chapel, and the very numerous and elaborate modern examples, all imitated from the best old examples, in the New Palace, Westminster.

The sedilias, piscinas, stoups, and other recessed features of Gothic ecclesiastical buildings, are usually so treated as to be in fact niches, though having their proper names they are not so classed.

NICKEL (Ni). A well known elementary metal. It is extensively used in the manufacture of the so-called *nickel-silver*, GERMAN-SILVER, and similar white alloys. Its natural history and physical properties together with the source and composition of its ores have already been described. [NICKEL, in NAT. HIST. DIV.] A method of reducing nickel from its natural combinations has also been given, but on account of the increasing demand for it, greater attention has of late years been paid to the metallurgy of this metal, and the following process is, according to Louyet, the one now generally adopted in Birmingham. Speiss, an arsenio-sulphide of nickel and other metals, obtained in the manufacture of smalt [COBALT], is first fused with chalk and fluor spar and the resulting metallic mass reduced to powder and roasted to expel arsenic; the residue is then treated with hydrochloric acid, and bleaching powder gradually added to the solution till the iron is peroxidised. Milk of lime being now cautiously poured in the iron is thrown down as peroxide, any traces of arsenic being carried

down with it; the clear liquid is treated with a current of sulphuretted hydrogen to precipitate copper, bismuth, and lead, and the cobalt got rid of as peroxide by a second addition of solution of bleaching powder. Finally the nickel is precipitated as hydrated oxide by adding sufficient milk of lime, and the metal obtained on strongly heating, in a wind furnace, a mixture of black flux and the dried oxide.

The equivalent of nickel is 29.54 and its specific gravity, 8.82.

Oxygen and Nickel combine in two proportions, forming the protoxide and sesqui-oxide or peroxide.

Protoxide of Nickel (NiO) may be obtained by adding potash or soda to a solution of any salt of nickel, by which a green hydrate (NiO, HO) is precipitated; this, heated to redness, loses water and becomes of a dark olive-green colour. It may also be procured by heating nitrate of nickel to redness. It is insoluble in water, readily dissolved by most acids, and yields green solutions. It is not reducible to the metallic state by heat alone, and is not attracted by the magnet. When fused with borax a hyacinth-yellow bead is produced, becoming lighter in colour on cooling. Oxide of nickel is insoluble in potash or soda, but readily dissolves in ammonia; the solution has a fine azure-blue colour, and is decomposed by potash or soda. It is the base of all the salts of nickel.

Peroxide of Nickel (Ni_2O_3) may be obtained by adding a solution of chloride (hypochlorite) of soda to one of nitrate of nickel, or by transmitting chlorine gas through water in which hydrate of nickel is suspended. The peroxide thus obtained is of a black colour, insoluble in dilute acids, potash, or soda. When added to a mixture of ammonia and its carbonate, nitrogen gas is evolved, and the peroxide, becoming protoxide, is dissolved. With hydrochloric acid it gives out chlorine gas, and forms chloride of nickel. At a red heat it yields oxygen gas.

Chloride of Nickel (NiCl) is formed by dissolving either the protoxide or peroxide of the metal in hydrochloric acid. Its colour is a fine emerald-green; and by evaporating the solution, green filamentous crystals containing water are formed. This salt deliquesces in a moist atmosphere. When deprived of water it has a yellow colour and a micaceous appearance; it is volatile, and when sublimed at a high temperature is obtained in beautiful golden-yellow crystalline scales. Its solution is decomposed by the alkalies and their carbonates, but ammonia added in excess redissolves the precipitate at first formed.

The *fluoride* (NiF), *bromide* (NiBr), and *iodide of nickel* (NiI), are of but little importance. The bromide and iodide form hydrated salts containing six equivalents of water.

Sulphur and Nickel combine in three proportions, forming the sulphide, disulphide, and bisulphide.

Sulphide of Nickel (NiS) is prepared either by heating metallic nickel or the oxide with sulphur; or it may be procured by adding a hydrosulphate to a solution of nickel. The precipitated sulphide is nearly black, and dissolves in hydrochloric acid with the evolution of hydrosulphuric acid gas; the sulphide procured in the dry way is of a grayish-yellow colour, and requires aqua regia (or nascent chlorine) for solution. Sulphide of nickel is also found native. [NICKEL, in NAT. HIST. DIV.]

Disulphide of Nickel (Ni_2S) may be prepared by transmitting hydrogen gas over sulphate of nickel at a red heat. Its colour is lighter, and it is more fusible than the sulphide.

Bisulphide of Nickel (NiS_2). Carbonate of nickel is strongly ignited with sulphur and carbonate of potash, and the residue well washed with water. It is soft to the touch, and of dark iron-gray colour.

Phosphide of Nickel (NiP) is formed by the action of phosphorus upon nickel heated to redness; the resulting compound is whitish, brittle, and is decomposed when exposed to heat and air. It is more fusible than the metal, and, according to Pelletier, is composed of 17 phosphorus + 83 nickel; while Lampadius states its composition to be 13 phosphorus + 87 nickel.

Cyanide of Nickel (NiCy) is prepared by adding a soluble cyanide to a solution of nickel, or when hydrocyanic acid is mixed with acetate of nickel.

Ferrocyanide of Nickel is a grayish or greenish compound, which is precipitated when ferrocyanide of potassium is added to the salts of nickel. The *ferricyanide* is yellowish green.

Nitrate of Nickel (NiO, NO_3) may be prepared by dissolving either the metal or its oxide in dilute nitric acid. The solution is of a fine green colour, and by evaporation yields a deliquescent salt, containing six equivalents of water of crystallisation.

Sulphate of Nickel ($\text{NiO}, \text{SO}_3 + 7\text{Aq.}$) is easily procured by dissolving the oxide or hydrate in dilute sulphuric acid; a green salt is obtained, which readily crystallises in two different primary forms; first in rhombic prisms, and then by exposure to light in regular octohedra, the original crystals becoming opaque but retaining their prismatic outline. A *double sulphate of potash and nickel* ($\text{NiO}, \text{SO}_3 + \text{KOSO}_3 + 6\text{Aq.}$) readily crystallises out on evaporating a solution of the mixed sulphates.

The *carbonates of nickel* are mostly basic, containing variable proportions of hydrated oxide. They are precipitated when an alkaline carbonate is added to a solution of nitrate, or other salt, of nickel.

Alloys of Nickel:—

Arsenic readily combines with *Nickel*, and the compound remains undecomposed at a very high temperature. It does not obey the magnet.

Potassium and Nickel combine by fusion.

Antimony and Nickel form an alloy of a lead-colour.

Zinc and Nickel form a white brittle alloy, which enters into the composition of the *packfong* of the Chinese.

Tin and Nickel give rise to a white brittle alloy, which burns at a high temperature.

Cobalt and Nickel readily fuse together.

Mercury and Nickel have not been combined.

Copper, Zinc, and Nickel form a white alloy, of late years much employed under the name of GERMAN SILVER.

Iron and Nickel occur associated in meteoric stones. The following table exhibits the centesimal amounts of the two metals in some well authenticated specimens.

	1.	2.	3.	4.	5.
Iron . .	66.56	88.04	85.61	89.12	93.78
Nickel . .	24.71	10.73	12.28	8.26	3.81

1. From Clairborne in Alabama. 2. The Pallas meteoric iron from Siberia. 3. From Cap; specific gravity, 7.665. 4. From Levarto; specific gravity, 7.798. 5. From Bohumilitz in Bohemia.

Tests for nickel. The solutions of nickel salts have a rich green colour. They are distinguished by giving—no precipitate with sulphuretted hydrogen; black with sulphide of ammonium; green with a caustic alkali, not altering on exposure to air; and green with ammonia, forming in excess a bright blue solution.

Estimation of nickel. This is generally performed in the state of protoxide, which contains 78.69 per cent. of metal. It is precipitated from solution by potash, and must be many times washed with hot water to thoroughly remove all the alkali. According to Field, nickel is best precipitated as peroxide. The solution is boiled with hypochlorite of soda in a beaker, care being taken to prevent the peroxide attaching itself to the sides of the vessel. This precipitate is easily washed, and on ignition to whiteness is reduced to protoxide, and may in that state be weighed. Liebig separates nickel from cobalt by boiling the solution of their potassio-cyanides with finely levigated peroxide of mercury; the nickel salt is then decomposed and the hydrated oxide of that metal precipitated, while the cobalticyanide of potassium remains in solution along with cyanide of mercury.

NICKEL SILVER. [NICKEL, *Alloys of.*]

NICOLAÏTANS, a sect of heretics, who arose in the 1st century, and are mentioned with strong disapprobation in Rev. ii. 6, 15. They appear, from the statements of the early writers, to have held the doctrines of the Gnostics, and to have lived impurely. It is generally supposed that "the doctrine of the Nicolaitans" (Rev. ii. 15) is the same as "the doctrine of Balaam" (v. 14), namely, "to eat things sacrificed to idols, and to commit fornication." Indeed some critics suppose the name Νικολαος in this passage to be merely translated from נִזְבִּי and used symbolically, deriving the former word from νικᾶω and λαός , and the latter from the synonymous Hebrew words נָבִי and עַם . (Robinson's 'Greek Lexicon to the New Testament.')

The early writers trace this sect to Nicolas the Deacon (Acts vi. 5), but some of them acquit him of holding the sentiments of the Nicolaitans, and ascribe the rise of the heresy to an improper advantage taken of some incautious expressions which he had used.

(Mosheim's *Ecc. Hist.*; Winer's *Biblisches Realwörterbuch*; Neander's *Kirchengeschichte*.)

NICOTIA. [NICOTINE.]

NICOTIANA TABACUM, an annual plant, of which the leaves are used in a variety of forms and ways, and also in medicine. The dried leaves are large, long, entire, smooth, somewhat glutinous, and of a brown colour, with a peculiar stupifying odour, and an acrid, nauseous, bitter taste. The processes of maceration and partial fermentation, and admixture of different substances, render it more agreeable in the dried than in the fresh state. The analysis of tobacco shows its chief ingredients to be:—1st, a tobacco-camphor, called nicotian, or nicotianin, which crystallises, and is solid at the ordinary temperature of the air; has a faint odour of tobacco, with a warm, bitterish aromatic, but not acrid taste, and is not possessed of any narcotic power; if applied to the nostrils, it causes sneezing; and if a grain be taken into the stomach, it creates uneasiness and giddiness. It is called by some the acid principle of tobacco, and if such be its nature, it is most probably combined in the herb with, 2nd, nicotina, an alkaloid, which, like conia, does not exist at ordinary temperatures in a solid form, but in a fluid and volatile state, having an oily appearance.

The empyreumatic oil of tobacco appears to be formed during the destructive combustion, and does not exist naturally in the leaf, but is probably formed at the expense of the nicotina. It does not therefore exist in the infusion of tobacco, the mode of action of which differs in several respects from the other forms in which it is employed. The products of tobacco when burnt, as in smoking, are:—carbonate of ammonia, nicotianin, empyreumatic oil, soot, and some gases.

Nicotina seems to be the formidable principle of tobacco when used in the solid form, or as an infusion; and the empyreumatic oil, when

it is smoked, or when obtained by destructive distillation. The action of nicotina is highly poisonous; a quarter of a drop will kill a rabbit; one drop can destroy a dog. It is distinguished from the other alkaloids obtained from the tribe of the *Solanaceae* by not causing dilatation of the pupil; the external application of it to the eye produces other very alarming narcotic symptoms. The tenth part of a grain put into the eye of a cat causes strong convulsions, with foaming at the mouth, quick respiration, accompanied with rattling in the throat and rapid palpitations of the heart, which can be heard at a considerable distance, staggering, and paralysis of the hinder extremities, which symptoms disappear in an hour.

The empyreumatic oil, in the quantity even of a single drop placed on the tongue, excites convulsions and coma, without affecting the heart. It may prove fatal in two minutes.

Tobacco, therefore, is a very powerful agent, the active principles of which are extracted by water, either in the form of infusion or decoction. The local effects of tobacco-leaves, or any preparation of them, are those of an acrid substance; hence when taken internally they cause vomiting and purging, pain of the stomach and intestines, followed by inflammation and ulceration. The external application occasions irritation of the part, and if kept long in contact with it, inflammation: snuffing the prepared powder induces sneezing and increased secretion of mucus; chewing or smoking it causes increased secretion of saliva, with diminished appetite in those unaccustomed to its use.

Besides these local effects it has a secondary action, which results from the absorption of the active principles. It is immaterial by what channel they are introduced into the circulation: the same consequences follow, and affect on the one hand the intestinal canal, the lungs, and the heart; and on the other, the nervous centres of the brain and spinal chord. The former show themselves by nausea, vomiting, purging, pain and inflammation of the stomach, and here and there of the intestines; on the lungs, by the slower, painful, and irregular respiration; and after death the tissue of the lungs is found to be thicker, more injected with blood, and accumulations or extravasation of it. The action on the heart, or probably the nerves of the heart, manifests itself by irregular, generally slower pulsations, and by the heart losing its irritability sooner than after natural death; but the chief secondary action is on the brain and spinal chord, and this succeeds the external as well as internal application of it, but most so after injection into the rectum. Giddiness, weight, and pain of the head; deafness, a feeling like intoxication, staggering, trembling, general weariness of the muscles, with convulsive contractions of them, or cramps, general insensibility, sleepiness, and death are the consequences.

Tobacco must therefore be considered as a narcotic acrid poison. Habit reconciles the system to its action when used moderately, but nothing can secure the body from its irritative property and its ultimate absorption when employed in excess or incautiously. Uncontrollable fits of sneezing have produced death, and smoking a number of pipes or cigars has also caused death. The use of an infusion as a wash to the head in ringworm, or against the itch, has produced death by absorption through the abraded surface. The greater number of fatal cases have resulted from the employment of it as an injection into the rectum, either against worms, or, by a most singular practice, in the form of smoke in the case of persons drowned, a custom which ought to be strongly censured and relinquished.

The few cases which can justify the use of so formidable an agent are those in which great relaxation of the muscles is wished, such as to reduce dislocations or hernias, or to remove obstructions in the intestines, in ileus, and similar diseases. But the utmost caution is here requisite; and an injection of uniform strength, as ordered in the 'Pharmacopœia,' is to be prepared, and thrown up in divided portions, under the direction and in the presence of the medical attendant. In case of over-dose, vital stimulants, such as brandy or ammonia, must be resorted to. Tobacco is now nearly entirely superseded by chloroform in such cases. The infusion of tobacco has been recommended as a diuretic in some cases of dropsy; but it is a dangerous remedy, and seldom employed.

Against the common use of tobacco for snuffing or smoking it is perhaps useless to declaim. Chewing it is limited in a great measure to sailors, and it were to be wished that the practice of smoking were similarly restricted. The evils which follow indulgence in these customs are not very obvious, but that injury results in most cases is certain. [ANTIDOTES; ERRHINES.] Tobacco is largely sophisticated. These are frauds on the revenue, or on the purchaser, but not many of them are dangerous. Snuff, however, is adulterated at times with lead. The use of such adulterated snuff produces paralysis of some of the facial nerves.

NICOTIANIN, or *essential oil of tobacco* ($C_{40}H_{52}N_2O_6$).—A crystalline substance that slowly separates from the liquid obtained on distilling tobacco leaves with water. It somewhat resembles camphor, is volatile, insoluble in alcohol or ether, has a feeble odour resembling tobacco smoke, an aromatic bitter taste, and according to M. Barral, should give nicotine by distillation with potash. It seems to exist in tobacco in but very small quantity.

NICOTIC ACID ($C_6H_2O_6, 2HO$). A peculiar acid allied with oxalic acid, and said to be contained in tobacco juice. It crystallises in

micaceous scales, but its existence as a distinct acid cannot be considered as established.

NICOTINE, *Nicotia* ($C_{10}H_7N$).—This alkaloid is the active principle of TOBACCO. [NICOTIANA *tabacum*, in NAT. HIST. DIV.] It was first discovered by Vauquelin in 1809, and probably exists naturally in the state of malate or citrate. It may be isolated by several methods; the following being the one proposed by M. Debize. A mixture of lime and tobacco is placed in a cylinder and a current of heated steam passed through it. The opposite end of the cylinder to that at which the steam enters is connected with a worm, by which the steam, nicotine, ammonia, and some undefined bases are condensed. In order to separate the nicotine, the condensed liquid is neutralised with sulphuric acid, concentrated by evaporation, and then treated with ether and ammonia. In this way an ethereal solution of nicotine is obtained, from which the alkaloid can be easily separated and purified by rectification.

The proportion of nicotine in the different kinds of tobacco varies considerably. According to M. Schloesing, the centesimal amounts in some of the French and American tobaccos are as follows:—

Lot	7.96	Alsace	3.21
Lot-et-Garonne	7.34	Virginia	6.87
Nord	6.58	Kentucky	6.09
Ille-et-Vilaine	6.29	Maryland	2.29
Pas-de-Calais	4.94	Havannah, less than	2.0

In the manufacture of snuff, much of the nicotine is decomposed; seldom more than two per cent. remaining unaltered.

When tobacco leaves are burned the nicotine—or at all events the greater part of it—passes off along with the smoke, and in the impure state may be frequently seen condensed in oily drops in the stems of tobacco-pipes.

When pure, nicotine is a colourless oily liquid, of sp. gr. 1.027. It has a pungent, irritating smell, and persistent burning taste. It is exceedingly poisonous, one drop being sufficient to kill a large dog. Its chemical characteristics are such, that it can readily be detected in the stomach and blood of any animal that has swallowed a sufficient quantity to produce death. Exposed to the air, nicotine absorbs oxygen, becomes brown, and is ultimately converted into a solid resinous substance. Its boiling point is 480° Fahr., nevertheless it is so volatile at ordinary temperatures, that if one drop is spilt in a moderate-sized room, the atmosphere is rendered so irritating as to be scarcely respirable. It is also readily distilled with the vapour of water, or in a current of hydrogen. Ignited in the air it burns with a bright smoky flame. It is very soluble in water, alcohol, ether, and the fixed oils, only slightly so in turpentine, and is very hygrometric. On agitating its aqueous solution with ether, the latter extracts the whole of the nicotine, and forms, on standing, a layer on the surface of the water. Solutions of nicotine exert lævo-rotation on a ray of polarised light: their chemical properties are very similar to those of ammonia, but may be distinguished by giving a reddish-yellow precipitate with chloride of gold, very soluble in excess of nicotine; a blue precipitate, changing to green, with chloride of cobalt; yellow precipitate with aqueous solution of iodine; and an abundant white precipitate with pure tannic acid. The odour of nicotine, though tested for in the same way as for ammonia, is very different from the latter body.

Nicotine, like ammonia, is a powerful base combining with acids to form salts. It also yields iodine and methylic, ethylic, &c., derivatives. From the experiments of Kekulé and Von Planta and others, it appears that nicotine belongs to the class of nitrile bases, and is, in fact, ammonia in which the three equivalents of hydrogen are replaced by the ter-atomic radical *nicotyl* ($C_{10}H_7'''$).

Hydrochlorate of nicotine ($C_{10}H_7N, HCl$).—This salt is very deliquescent, but may be obtained in long fibres by the action of dry hydrochloric acid gas upon nicotine. **Sulphate of nicotine** is uncrystallisable. **Phosphate of nicotine** crystallises in large plates resembling cholesterin. **Oxalate of nicotine** is exceedingly soluble in water, but may be obtained in crystals; it is also soluble in boiling alcohol, but insoluble in ether.

Chloroplatinate of nicotine ($C_{10}H_7N, HCl, PtCl_2$) is a yellow crystalline precipitate produced on adding bichloride of platinum to an aqueous solution of nicotine neutralised with hydrochloric acid. It is very soluble in excess of nicotine; dilute hydrochloric acid also dissolves it when gently warmed, and redeposits it in oblique rhomboidal prisms. Several *chloromercurates of nicotine* exist.

Iodonitine ($2C_{10}H_7N, I_3$) is formed on mixing together ethereal solutions of nicotine and iodine; from a dilute solution it slowly deposits in beautiful ruby-red needles. Potash decomposes it with liberation of nicotine. Hydrochloric acid combines with it to form rich ruby-red plates, containing ($2C_{10}H_7NI_3, 3HCl$).

Methylic, ethylic, and amyllic derivatives of nicotine.—These bodies correspond to ammonium (NH_4) in which which three atoms of hydrogen are replaced by nicotyl, and the remaining one by methyl or its homologues. Their *iodides* are produced by the direct action of the iodide of the radical upon nicotine, the *hydrated oxides* being formed when the iodides are treated with recently precipitated oxide of silver. The hydrated oxides are powerful caustic bases resembling potash and soda; they perfectly neutralise acids, forming salts that are mostly crystalline precipitate the oxides of copper and of iron from

their salts; and dissolve recently precipitated alumina with facility. The names and formulæ of some of them are as follows:—

NICOTYL. [NICOTINE.]

NIELLO is a method of ornamenting metal plates, practised chiefly during the middle ages. Upon the plate—which was most commonly of silver, but sometimes of gold or copper—the design was first sketched with a style, and then somewhat deeply engraved with a burin or graver. [ENGRAVING.] The lines thus incised were filled with a composition called from its colour *nigellum* (whence the Italian *Niello*), and, the plate being polished, an effect was produced something like that of a pen-and-ink drawing. The composition was an amalgam of quicksilver, silver, and lead, (with occasionally a little copper) melted together, and blackened by the addition of sulphur. When cold the *nigellum* was pounded and kept ready for use. This powder was laid, with borax, on the incised lines, into which it was melted by a gentle heat being applied to the back of the plate, which when cold was polished and burnished, and the work was complete.

This kind of engraving is of considerable antiquity. It appears to have been practised in the early centuries of Christianity by the goldsmiths who prepared the more costly articles for ecclesiastical purposes. Two small gold cups which had in the centre crosses in niello were bequeathed by the Abbot Léodebode to the convent of St. Aignan d'Orleans in the 7th century. At the beginning of the 9th century a pectoral cross, of which one side was decorated in niello, was sent by Nichephorus, patriarch of Constantinople, to Pope Leo III.; and towards the end of the same century, various articles of silver engraved in niello were made at Constantinople for the church of St. Mark at Venice. The art in these early times seems to have been chiefly practised by Byzantine artists; but in the 10th century we find it practised both in Italy and Germany, though the workmen may possibly have been Greeks. From the 12th century niello seems to have formed a regular part of the goldsmith's art, and it was applied to the ornamentation of a great variety of articles, as well for secular as for ecclesiastical purposes. The Italian goldsmiths especially acquired great skill in the art, and produced works of exceeding beauty of design and execution.

As mentioned under ENGRAVING, niello is regarded as the parent of engraving in the modern sense of the term, that is, for taking impressions on paper. The application is usually ascribed to Maso Finneguerra, the most famous of the Florentine workers in niello. In order to observe the progress of their work the niellatori were accustomed to take casts from it at various stages in clay, upon which they poured melted sulphur, and thus obtained fac-similes of their engraving. Into these lines in the sulphurs, as they are called, they rubbed a composition of oil and lamp black, and were thus able to judge of the appearance of the plate after the insertion of the *nigellum*. According to Vasari, and other Italian authorities, it occurred to Finneguerra that he might save himself much of this troublesome process by filling the lines in the original plate with a similar composition, and taking impressions directly from it upon damped paper. Not only was his experiment successful, but these impressions on paper soon grew to be so much in request that niellatori found it a profitable occupation to prepare plates especially for their production; and their extension to the imitation of paintings and drawings soon followed, and engraving became a distinct profession. At the same time, however, the working in niello proper seems to have declined; since Benvenuto Cellini relates that by 1515 the method of executing niello was nearly forgotten in Florence, when he, stimulated by the admiration expressed for the nielli of Finneguerra, applied himself with great diligence and entire success to the restoration of the lost art. Of this period many beautiful works, including suits of armour and other large articles, adorned with nielli are still extant, as well as numerous smaller articles. The art, however, gradually passed out of use, and old nielli are now comparatively rare, and placed among the most precious articles of public and private collections. Among the public museums, the British Museum is one of the richest in nielli, and in impressions in sulphur and on paper—having about 70 silver plates, including some of extreme rarity and beauty of style, several fine sulphurs, and above a hundred proofs on paper, some of which are unique. Reference has been made to these last in the article ENGRAVING: it will be enough therefore to add that a case has recently been placed in the King's Library, open consequently to public inspection, which contains some of the finest of nielli, sulphurs, and proofs, so arranged as to illustrate the history of the art, and its connection with that of engraving. The national museums at Paris, Vienna, Berlin, and Dresden, are also rich in nielli.

NIGELLIN, a non-azotised extractive matter, of unknown composition, obtained from the seeds of the cultivated *nigella*.

NIHIL ALBUM, an old alchemical name applied to the exceedingly light oxide of zinc obtained by burning the metal in air. [ZINC, OXIDE OF.]

NIMBUS. The terms Nimbus, Aureole, and Glory are often used indifferently for the marks of divinity or sanctity which encompass the person or encircle the head of figures in early art; but they have a well-marked distinction, the observance of which is important in Christian iconography. The term *Nimbus* is strictly confined to the disk or halo which surrounds the head; *Aureole* to that which envelopes the entire person; while *Glory* is by the best authorities applied to the union of both.

The nimbus, or a corresponding attribute, is of great antiquity. It is found alike in the art of India, Egypt, and Greece. Its origin is supposed to be the East. Ciampini and Wilkinson point to the disk on the head of the Egyptian god Re, or the sun, as the original of the nimbus. A nimbus or aureole is seen surrounding the Hindoo goddess Maya. From the Egyptians the nimbus was borrowed by the Greeks for their sun-god Apollo. It occurs also on Etruscan vases; and in paintings found at Herculaneum and Pompeii, Roman divinities and heroes are seen with nimbi almost identical with those of the sacred personages in mediæval art.

It is frequently said that the nimbus was derived from a custom which prevailed in classic times of placing a disk of metal over the head of statues of the gods to save them from defilement by birds, &c.; but, as we have seen, both the nimbus and aureole were of a date long anterior to the classic period, and it is only in late examples that the nimbus is placed above the head like a protecting disk. There can be little doubt that, as M. Didron suggests, the original idea of the nimbus and aureole was that of an emanation of light or flame, its signification that of power. The same idea seems to have been common to all the Arian races, and was probably derived from the primitive worship of the sun. Thus, as we have seen, in its oldest known form it was the attribute of the Egyptian sun-god Re, as it was afterwards of the Greek Apollo. The same conception is indeed sanctioned in the sacred Scriptures, where we in various great manifestations find the presence of the divine power expressed by an emanation of light. David, for example (Ps. civ. 1-4), speaks of the Lord as "clothing himself with light as with a garment," the idea evidently intended to be conveyed by the aureole; the face of Moses, when he came down from Mount Sinai (Ex. xxxiv. 29-35), shone with unbearable light—an idea sought to be conveyed by the nimbus; while in the New Testament (Luke ix. 31, 32) we are told that our Saviour at his Transfiguration appeared "in his glory, his raiment white and glistening," to the disciples who accompanied him on the mountain.

Passages like these, as they are quoted to sanction the application of one or other forms of the glory to the holy personages of the Christian Church, might almost seem to have suggested their use, had we not evidence that they were generally employed in pagan times, and that they were in fact mere appropriations by Christian artists from pagan art. Neither the nimbus nor the aureole is seen in the earlier Christian iconography. The nimbus first appears in miniatures of the latter part of the 5th century; the aureole not till some time later. Both continued in use in miniatures, mosaics, sculpture, and painted windows throughout the middle ages, only giving way before the revival of classic art in the 15th century, and disappearing in the 16th; the aureole, as it had been latest introduced, being the first to be abandoned.

By the mediæval ecclesiastics and artists, a great extension was given to the use of the nimbus, and much importance attached to it. No longer was it merely the emblem of deity, but the general attribute of ecclesiastical apotheosis. The broad distinction was however maintained that, whilst the nimbus was common to all who were thus distinguished, the aureole was confined to the three persons of the Trinity and the Virgin Mary: the varying forms and symbolism of these attributes are among the most important points in the study of Christian iconography.

The nimbus is most commonly circular; but it occurs in a great variety of forms, depending partly on the time or country, partly on the symbolic idea, often no doubt only on the individual taste or fancy of the artist: sometimes (in the Father and the Son) triangular, or as a double triangle; hexagonal; lozenge-shaped; as a roll partially unfolded; like a triptych; and even square, but this only in the case of bishops and other churchmen represented whilst yet alive. Sometimes the nimbus of the three persons of the Trinity consists of an emanation of light without a circumscribing outline, the rays forming the three arms of a cross; but usually the outline is added. These cruciform rays are confined to Deity. Sometimes the nimbus is opaque, with a broad ornamented border (that of the Virgin, for instance, is often very richly adorned), or the border contains the name of the person represented; sometimes, and especially when art was passing out of the region of symbolism, it was transparent; and before its entire disappearance, as in some of the pictures of Raffaele and his contemporaries, there is only the faintest indication of a nimbus, and that, instead of encircling the head, is placed above it. The nimbus is usually of gold,—that of the divine personages and of the Virgin almost invariably so,—but sometimes it is otherwise coloured (blue, red, purple, white) in the case of apostles, saints, and other holy persons. The colour is regarded in many of these instances as sym-

bolical: Didron mentions a Judas with a black nimbus. The persons who in mediæval art are represented with the nimbus are, as has been seen, the three persons of the Trinity, the Virgin, angels, the patriarchs, prophets, apostles, &c., of the Old and New Testaments, and all who had been canonised by the Church. But princes, popes, and bishops, living as well as dead, likewise frequently bear this attribute of apotheosis, though they could have no such claim to it. It is often figured also on symbolical animals, as the lamb, the beast with seven heads of the Apocalypse, &c.; and a hand encircled with a nimbus which has the cruciform rays is a well-known symbol of the Father; but the hand when stretched forth from a cloud has frequently, instead of a nimbus, a stream of light issuing from it. The Hebrew word Jehovah is often painted on a triangular nimbus.

The aureole, as has been said, instead of encircling the head only, like the nimbus, encompasses the entire person. It is confined, with rare exceptions, to the Trinity and the Virgin Mary: the exceptions are mostly of late date, and comprise such representations as the souls of certain saints, or the Magdalene in an ecstasy. The usual form of the aureole is a pointed oval, formed by the intersection of circles of equal diameters. This is commonly termed a *Vesica piscis*, from a fancied resemblance to the form of a fish, which in its turn was supposed to be symbolical of the Saviour, from its name in Greek ($\chi\theta\upsilon\varsigma$) containing the initial letters of the names and titles of Jesus Christ. But this is probably a strained fancy. There can be little doubt that the oval form of the aureole was given to it from the outline circumscribing the rays of light emanating from the divine person most readily assuming that regular form, as the outline circumscribing the rays emanating from the head would naturally take the circular shape of the nimbus. Sometimes the aureole is contracted at the neck and angles of a standing figure. Around a seated figure it becomes circular in form, or occasionally takes the shape of a quatrefoil. In Byzantine art it is seen circular, with rays or lines diverging from the centre, so as to resemble a wheel. Some miniatures show the aureole like an encircling cloud. French artists frequently gave the outline a wavy appearance; and other divergences from the regular form might be mentioned. The aureole is, like the nimbus, commonly gold; but it is frequently coloured. Sometimes, for instance, when the Father is represented within the aureole, his feet resting on a rainbow, the ground of the aureole is azure, and powdered with golden stars. At first the aureole, like the nimbus, had an enriched border; but in the 15th century the border was first diminished, and then omitted, the aureole itself soon after ceasing to be represented.

With the recent revival of mediævalism, both the nimbus and aureole have reappeared in ecclesiastical art. Even in Protestant churches they are now almost universally figured, and the nimbus is not confined to the saints of the Scriptures: thus "King Charles the Martyr" is represented with the nimbus in a stained glass window erected a few years ago in Kilndown Church, Kent.

(The fullest information respecting the nimbus and aureole will be found in Didron's *Iconographie Chrétienne*; but Mrs. Jamieson's *Sacred and Legendary Art*, and works of a similar class, should also be consulted; while D'Agincourt's *Histoire de l'Art par les Monumens*, will, with the works just named, supply an ample number of examples.)

NINEVEH, ARCHITECTURE OF. Until the year 1843, the very sites of the great cities of the mighty Assyrian empire were little more than matter of conjecture. Rude mounds of earth, and huge heaps of unburnt brickwork, served to stimulate the wonder of travellers and the curiosity of archæologists; but the most searching investigations of travellers like Rich and Niebuhr did not suffice to remove the obscurity which involved the question of where stood Nineveh and Babylon, and what was the character of their buildings? The wondrous extent of the cities, and the magnificence of their architecture, were attested alike by the Old Testament scriptures, and by Greek historians and geographers [*NINEVEH*, in *GEOG. DIV.*], but neither the one nor the other supplied the means of reproducing with the faintest approach to certainty, any of these vast edifices. The explorations of Messrs. Botta and Layard, in 1843 and following years, and of those who succeeded them in their labours, however, brought to light sufficient to prove the accuracy of the contemporary accounts of the splendour of the Assyrian palaces, and to enable the accomplished architect to reproduce with tolerable distinctness the buildings themselves.

The excavations which yielded such marvellous and unexpected results, were carried on chiefly at Nimroud, Khorsabad, and Kouyunjik, situated on the east bank of the Tigris nearly opposite Mosul, and within a district about 30 miles in length; and, as Mr. Layard, the great authority on the subject, believes, all forming at one time portions of the same great city: "the numerous royal residences, surrounded by gardens and parks, and enclosed by fortified walls, each being a distinct quarter known by a different name, formed together the great city of Nineveh," though by others they are rather regarded as separate cities. In all ten great buildings have been discovered, and all of them have precisely the same character, being palaces, or rather palaces and temples combined, the king having a sacred character, and being chief priest as well as governor. Nineveh was founded some 2000 years B.C.; but the oldest building yet discovered appears, from inscriptions on it, to have been built in the reign of Sardanapalus, B.C. 930, the latest was hardly finished at the destruction of the city, B.C.

625; the architectural examples therefore extend over a period of 300 years, but leave the archaic period unillustrated.

The palace-temples of Nineveh yet discovered were all built on an artificial mound or platform raised 30 or 40 feet above the level of the ground. These mounds or terraces were of vast extent; that of the palace of Sennacherib at Kouyunjik was a mile and a half in circumference. They were partly of earth and rubbish, and partly, or, as at Khorsabad, wholly of regular layers of sun-dried bricks cemented together with clay, faced with slabs of stone, and supported by solid masonry. The object in raising these costly substructures was probably, as Mr. Layard suggests, to secure a certain amount of coolness during the summer heats, as well as to impart dignity to the building, and afford a means of defence. The process of raising these mounds, and of erecting the buildings, is minutely depicted in the marble slabs brought from the buildings themselves, and now deposited in the British Museum and the Louvre.

The buildings appear to have consisted of a series of chambers invariably rectangular, and usually oblong, placed side by side, and with studious symmetry around great halls or square open courts. These chambers occur from one to two hundred feet in length, and from twenty to forty in breadth. From this great central block suites of smaller rooms project as wings, the rooms decreasing in size and richness as they recede from the centre. In some of the palaces long galleries connect the several parts. The great halls and courts, with some of the chief apartments, appear to have been devoted to purposes of state and ceremony; while other portions were, as Mr. Fergusson has shown, set apart in accordance with eastern habits for the use of the females, or, as it would now be termed, the harem.

Both externally and in the interior, the palaces were of extraordinary magnificence. The approach to the building was at Khorsabad, and perhaps elsewhere, if Mr. Fergusson's restorations be correct, by way of an outer and lower mound, "on which were situated the great portals of the palace, and the residence of the guards and inferior officers; and beyond even this, on the plain of the city, a set of interportals are found, from which the great winged bulls, now in the British Museum, were taken." Passing these portals a flight of steps led up to the palace. The building itself was nearly square, with two principal façades, one of which, where the palace was built by the Tigris, usually overlooked the river; the other was on the opposite side. Each front had three entrances, the principal being in the centre. The sides, or jambs of the central portals, were formed by slabs, on which were sculptured colossal human-headed and winged bulls, 16 or 18 feet high; the side doorways being usually guarded by colossal figures of divinities or kings, but in some instances by winged-bulls similar to those of the chief entrance. Between the doorways, pairs of these winged-bulls, of somewhat smaller size, were placed back to back, with sometimes colossal human or symbolical figures between them. The rest of the walls, to the height of about 9 feet, were faced with slabs, on which were carved single figures or groups, of the kind familiar to every one, by the examples in the British Museum or the popular works of Layard, Bonomi, and others. The walls themselves, which were of immense thickness, were built of sun-dried bricks; the sculptured slabs are chiefly of calcareous stone or alabaster. Of the actual buildings, only these lower sculptured walls, with a few feet of the brick surface above, remain.

The character of the upper part of the building is conjectural. But following out the indications on the extant parts, it seems pretty evident that the brick walls were carried up at least to the height of the great bulls, or about 18 feet, the surface being covered with stucco, and painted with various figures of the king and his attendants, mythological subjects, &c., or in conventional patterns. From large quantities of charred wood being found within the chambers, and no remains of a stone or brick superstructure, it is conjectured that the superstructure, of whatever description it was, was constructed chiefly or wholly of wood. This superstructure, Mr. Fergusson, who has more thoroughly studied the subject than any other authority, considers to have consisted of "a gallery or upper story to the palace; and thus in the heat of the day, the thickness of the walls kept the inner apartments free from glare, while in the evenings and mornings, the galleries formed airy and light apartments, affording a view over the country, and open on every side to the breezes that blow so refreshingly over the plains. It will thus," he adds, "be evident that the direct rays of the sun could never penetrate into the halls themselves, and that rain, or even damp, could easily be excluded by means of curtains or screens."

The roof Mr. Fergusson supposes to have been supported on low wooden columns, resembling in style those of stone still standing at Persepolis, and others recently found at Susa; grounding his opinion on the fact made evident by the discoveries at Nineveh, that the Persians in their architecture imitated that of the Assyrians; reproducing as well as they could, the winged-bulls and other characteristic sculpture, as well as the general form of the buildings, and, as is highly probable, copying in stone the wooden columns of their prototypes. No complete column, it must be understood however, has been exhumed among the Assyrian remains, but only fragments of bases, and none of these are of wood. In the reliefs which cover the walls of the Assyrian palaces, columns of various kinds occur, including, as it would seem, the original of the Greek Ionic; the open gallery, or

upper story is also distinctly indicated. From these, and from the Persepolitan columns, Mr. Fergusson conjectures that the wooden columns of the palaces of Nineveh, were short and thick, with carved shafts, and large capitals. A favourite form of the capital appears from the Assyrian reliefs and the existing Persepolitan examples to have consisted of two bulls set back to back. The columns are often figured as resting on winged bulls and lions placed back to back. The gallery was crowned by a curved cornice, which appears to have been richly adorned with conventional decorations, which are certainly the originals of the well-known Greek guilloche and honeysuckle ornaments. Surmounting the cornice was a stepped battlemented parapet of a pattern peculiar to Assyrian architecture.

The roof was of wood and flat, its framework being formed by massive beams which were borne by the columns. Several of these great beams of cedar and other woods have been found at Nineveh, some nearly perfect, but others reduced to charcoal, and crumbling to powder when exposed to the air. The exterior of the roof was probably composed, as is still usual, of five or six feet of earth,—a plan adapted to keep out alike heat and wet.

Internally the great halls, courts, passages, and principal apartments, were, like the exterior, faced with slabs of alabaster, on which were carved the battles and sieges of the great king, the capture of cities and the presentation of captives and hostages; hunting scenes; various divinities, the sacred tree, and other mythological and symbolical subjects, &c. In some of the secondary buildings, or less important chambers, the walls were covered with stucco, and painted either with figures similar to those of the reliefs or with conventional ornament. The pavement was formed of elaborately ornamented alabaster slabs or square tiles or bricks; both slabs and bricks bearing on their backs the name of the sovereign who erected the building. The ceilings were, as we know from the Scriptures, and as is proved by the remains, "ceiled with cedar and painted with vermilion," and probably adorned with gilding and inlaid with ivory. Traces of polychrome decoration are found everywhere. Both the exterior and interior walls, there can be little doubt, were painted with the most brilliant colours. Gold was profusely employed, and the images on the walls were "painted with vermilion, girded with girdles upon their loins, exceeding in dyed attire upon their heads, all of them princes to look to, after the manner of the Babylonians." (Ezek. xxiii. 14, 15.)

The buildings hitherto explored were, as has been said, palace-temples; but they also, as Mr. Layard observes, "appear to have been at the same time public monuments, in which were preserved the records or archives of the nation, carved on stone. In them were represented in sculpture the exploits of the kings, and the forms of the divinities; whilst the history of the people, and invocations to their gods, were inscribed in written characters on the walls." These inscriptions, in cuneiform characters, are carried over the surface of the larger reliefs, without any regard to the effect of the sculptured design; and since the learned have succeeded in deciphering the characters they have furnished valuable information respecting the history of the people, as well as the construction of these monuments. [CUNEIFORM.]

Buildings such as those we have been describing, however splendid and imposing in appearance, were ill-calculated to withstand violence and subsequent neglect. Whilst the still older temples of Egypt are, in their great features, as strong and impressive as ever, the preservation of any portion of those of Nineveh is due to their being buried beneath the soil. But the very constructive defect which hindered their permanent maintenance may have contributed to the preservation of so much of them as remains. The columns and superstructure being of cedar would be an easy prey to the flames, but then the thick roof of earth "would alone suffice to bury the building up to the height of the sculptures. The gradual crumbling of the thick walls consequent on their unprotected exposure to the atmosphere, would add three or four feet to this; so that it is hardly too much to suppose that green grass might have been growing over the buried palaces of Nineveh before two or three years had elapsed from the time of their destruction and desertion. When once this had taken place, the mounds were far too tempting positions not to be speedily occupied by the villages of the natives; and a few centuries of mud-hut building would complete the process of entombment so completely as to protect the hidden remains perfectly for the many centuries during which they have lain buried, and to enable us now to restore their form almost as certainly as we can those of the temples of Greece or Rome, or any of the great nations of antiquity." (Fergusson, 'Handbook of Arch.,' i. 178.)

In the work named below, Mr. Fergusson has, with scrupulous care and rare ingenuity, endeavoured to exhibit such a restoration. He has also, as our readers well know, given a more tangible shape to his speculations in the actual restorations, both in form and colour, of the Assyrian Court at the Crystal Palace, Sydenham. In the main, these restorations have met the sanction of Mr. Layard and other authorities who, like him, have made the antiquities of Assyria a special study. Without, therefore, pretending to say that all Mr. Fergusson's views are borne out by our present knowledge of Assyrian remains, and without wishing to be understood as adopting his polychrome theory, we point the reader to these actual restorations, with Mr. Layard's convenient little 'Guide' descriptive of them, as well as to Mr. Fergusson's larger treatise, as affording the readiest and surest means of acquiring

a definite conception of the leading characteristics of Assyrian palatial architecture. It may, however, be convenient to add a chronological list of the palaces discovered at or about Nineveh, adopting Mr. Layard's names of the founders and date of foundation.

The oldest is the North-West Palace, Nimroud, built about 900 B.C., by a king who is believed to be identical with the Sardanapalus of the Greeks. This, though not one of the largest, is one of the most beautiful of the palace-temples. The great hall is 152 feet long by 32 wide; at the upper end is the place of the throne, at the lower a vestibule overlooking the river. The façade was about 330 feet in extent. Like the other larger temples, the entire wall-surface, both inside and out, was faced with sculptured slabs, the best of which are now in the British Museum.

The Centre Palace, Nimroud, was built by a son of Sardanapalus, whose name has been read Shalman-bar, and who was contemporary with Jehu, king of Israel, who, according to the inscriptions on the palace, was tributary to the Assyrian king. Its date, therefore, is somewhere about 885 B.C. From finding slabs partly removed, and other appearances, Layard was led to conclude that this building had been despoiled to provide materials for building the South-West Palace, in which he found slabs identical in style and execution with those placed ready for removal in this.

At Kalah-Shergat, on the right bank of the Tigris, and perhaps the site of the Calah of the Scriptures, are the remains of a palace built by the founder of the Centre Palace. The mound is of unusual extent; but the palace contains, so far as is known, no sculptured slabs. A seated basaltic figure, now in the British Museum, was however found there.

The Upper Chambers, Nimroud, is a small palace, built about 800 B.C. by a successor of Shalman-bar, named Shamasphal.

The Palace at Khorsabad was one of the most remarkable of these palace-temples. It stood on a square mound, the sides of which were 650 feet long, and the approach was by a lower mound at least 1300 feet long and 300 feet wide. The great rooms were 116 feet long by 33 wide. The design is uniform throughout, and the sculpture of the best class of Assyrian art. It is from this palace that the sculpture in the Louvre is chiefly derived. The palace appears to have been wholly built by Sargon, about 720 B.C. The arch, both as a constructive and decorative feature, is shown to have been well understood by the Assyrians at this time.

The great Palace at Kouyunjik was built by Sennacherib, son of Sargon, about 700 B.C. This was the largest and most magnificent of the palaces of Nineveh. It stood on an artificial mound 7800 feet in circumference; the palace proper, which contained three great inner courts and above 60 apartments, occupying a square, the sides of which were 600 feet long. In extent it was only surpassed among the buildings of antiquity by the great temple of Thebes, and the entire wall-space was covered with sculpture. The chief of the slabs are now in the British Museum.

The South-West Palace, Nimroud, was built by Esarhaddon, the son of Sennacherib, who seems to have despoiled the previously-existing palaces, and especially the North-West Palace, for its decoration. The only part which appears to have been saved from entire destruction is the great hall, which is 165 feet long by 62 feet wide—the largest hitherto met with.

Another palace, supposed to have been built by the same king, was discovered in the mound known as the Tomb of Jonah.

A second great palace, discovered near that of Sennacherib, at Kouyunjik, appears to have been built about 650 B.C., by a son of Esarhaddon, named Asshur-bani-pal. It is characterised by greater minuteness and finish in the sculptured slabs and architectural details, but in other respects resembles the other large palaces. The sculpture is in the British Museum.

The South East Palace, Nimroud, is small, and comparatively unadorned, and is only interesting as having been built by a grandson of Esarhaddon, and probably the last sovereign of the dynasty.

Besides these palace-temples no great buildings, properly so called, have, as we have said, been discovered. But in the great conical mound at Nimroud were found the remains of a huge square tower, constructed of sun-dried bricks, which up to the height of about 20 feet had been faced with well-laid solid masonry. It appears to have risen in three or four stages or stories to the height of perhaps 200 feet; at the present time about 120 feet are still standing. In the centre of the structure was found a gallery, about 100 feet long, 6 wide, and 12 high; it was quite empty, and afforded no clue to the original purpose of the building. Mr. Layard is inclined to believe it a place of royal sepulture, and that it was the tomb of Sardanapalus, so often referred to by ancient writers: Mr. Fergusson thinks that it was a temple. Another more strictly pyramidal seven-storied building was found by M. Place: it appears to have been a temple, resembling that at Babylon known as the Birs Nimroud. An object of great interest found in this mound was a large inscribed and sculptured monolithic obelisk of black marble, now in the British Museum. [OBELISK.]

The city wall, which, according to Diodorus Siculus (b. ii., c. 1) was 100 feet high, and so wide that three chariots might be driven abreast upon it, and which was defended by 1500 towers, each 200 feet high, has not been traced: nothing now remaining of it, says Mr. Layard, "but the long lines of mounds enclosing the ruins of Nimroud,

Khorsabad, and Kouyunjik." But among the discoveries made by M. Place at Nineveh was that of one of the city gates. These appear to have been constructed in pairs of about equal width, from 12 to 15 feet; one gateway being devoted to wheeled carriages, the other to foot passengers, as is shown by the deep lines cut by the wheels in the pavement of the one, while that of the other is quite smooth. The foot passengers' gate is ornamented with slabs of human-headed winged bulls, alongside of which stand colossal figures strangling lions. The carriage gateway has plain slabs. Both have semicircular arches, with elegantly adorned archivolts formed of blue enamelled bricks with yellow figures.

The private residences, being constructed of sun-dried bricks, have entirely perished.

Babylonian Architecture.—Of the buildings of Babylon no complete example remains. Long before Layard or Botta began to excavate the buried Nineveh, Babylon had been the scene of frequent and careful, though by no means fruitful, explorations. The remarkable results of the researches at Nineveh led to a renewal of the investigation; but the success has been far from commensurable with the labour, and there is little reason to look forward to happier results at a future time. Like the ordinary dwellings of Nineveh, the buildings of Babylon were constructed entirely of brick, and where vast masses of brickwork remain they have utterly lost their form as buildings. The great mounds, which now comprise all that remains of the magnificent structures which excited the wonder alike of the ancient Hebrews and the polished Greeks, have been so fully described elsewhere [BABYLON, in GEOG. DIV.] that here a very brief notice will suffice.

The chief of the existing remains is that standing on the western side of the Euphrates, and known as the Birs Nimroud, a conical mound, formed of bricks, clay, and broken pottery, 762 yards in circumference, and at the western end rising to a height of 198 feet. On this summit is a solid structure of brick, 37 feet high and 28 feet broad, but diminishing to the top, which is broken and irregular. [See the cut and description in the article BABYLON, before referred to.] The building on the top is constructed of kiln-burnt bricks, and is in the best style of Babylonian brick-work; fragments of stone, marble, and basalt scattered about, show that it was adorned with more costly materials. The only openings are square holes pierced through the solid structure. By most writers it has been supposed to be the Temple of Belus, described by Herodotus; but there were always difficulties about the identification of the site, and the recent investigations of Sir H. Rawlinson have shown it to be a different building. Sir Henry, on discovering the angle of the basement wall by sinking a shaft, at once directed the workmen to look at a particular spot near it for a recess in which would be found a commemorative cylinder. This was done, and a cylinder covered with inscriptions [CUNEIFORM] was drawn out. A similar hollow with a duplicate cylinder in it was discovered near the opposite angle. On translating the inscription it was found to state that this building, the Temple of the Seven Spheres, which was built 504 years before (about 1100 B.C.), having become ruinous owing to the neglect of the drainage, the god Merodack had put it into the heart of the great King Nebuchadnezzar to rebuild it all but the platform which had not been injured. The building would appear from the investigations of Sir H. Rawlinson, to have consisted of a square basement about 360 feet on each side, and 6 feet high, on which stood a pyramidal structure of six stories, each about 20 feet high, and 42 feet less in horizontal extent than that on which it stands. These stories instead of being concentrically above each other, recede regularly, so that the front of the tower on the summit is above 200 feet from the front line of the basement, while the back is less than 100 feet from the rear line. The sides recede equally. The tower which crowns the summit, and which is spoken of above, was probably in two stories, and surmounted with a cornice. Within it was probably the shrine or holy place of the temple. In the front of the temple were steps leading from story to story from the basement to the tower at the summit. The seven stories, or platforms, were, Sir Henry believes, dedicated to the seven planets, and coloured with the colours attributed to them by the Sabeian astrologers. The lowest platform was panelled and painted black, the colour emblematic of Saturn; the second orange, the colour of Jupiter; the third red, Mars; the fourth gold, as dedicated to the Sun; the fifth green, for Venus; the sixth blue, Mercury; and the highest white, as the colour of the Moon, whose place was the highest in the Chaldean system. This remarkable discovery accords not only very closely with the descriptions of Greek writers, but in general form with figures on slabs found at Kouyunjik, and is probably therefore nearly correct.

The mound called the Mujelibé, by Rich, or the Mount of Babel by Layard [described under BABYLON in GEOG. DIV.], seems to be the site of a great palace resembling, probably, in its general character the palaces of Nineveh; but it appears to be too utterly ruined to admit of any very definite restoration. The Kasr of Rich, Layard (who calls it the Mujelibé) conceives to have been a fortified palace. There are numerous other mounds, but they yield no insight into the peculiarities of Babylonian architecture; which, therefore, in the absence of any evidence to the contrary, we may fairly suppose to have been in its general characteristics, analogous to that of Nineveh. Its chief difference arose probably from being built wholly of brick. Instead of the walls of the façades and the interior being faced with sculptured slabs

ARTS AND SCI. DIV. VOL. V.

of alabaster, they were covered with fine moulded bricks or stucco, and painted with representations of a similar kind to those at Nineveh, but perhaps even more gorgeously coloured.

The architecture of Babylon was contemporaneous, or nearly so, with that of Persepolis and Passargadæ; and thus, as Mr. Fergusson suggests, her palaces may have "formed the link that would enable us to connect, in a satisfactory manner, the edifices and architecture of Assyria with those of Persia." It is noteworthy that none of the bricks found in or about Babylon are earlier than Nebuchadnezzar; in fact all, or nearly all, are inscribed with the name of that monarch.

Other mounds and heaps of brickwork are found at Mugheyr and Wurka in southern Babylonia; but they do not seem likely to throw much additional light on the architecture of the country. Two of the buildings at Wurka appear to have been palaces; but the most extensive of the mounds must, from the numbers of tombs and coffins found in it, have formed for centuries a vast cemetery.

(Layard, *Nineveh and its Remains*, 8vo; *Monuments of Nineveh*, fol.; Fergusson, *Palaces of Nineveh and Persepolis Restored*; and *Handbook of Architecture*; Bonomi, *Nineveh and its Palaces*, 8vo; Botta and Flandin, *Monument de Ninive*, 5 vols., fol.)

NINTH, an interval in music, a discord retarding the 8th, but may be resolved into either the 6th or the 3rd; and though this is the octave of the 2nd, yet it is essentially different in harmony, both as to treatment and effect. [CHORD; THOROUGH-BASE.]

Of this interval there are two kinds; the major 9th, composed of six tones and two semitones—

and the minor 9th, composed of five tones and three semitones—

NIOBE, the daughter of Tantalus, king of Lydia, was married to Amphion, by whom she had, according to Ovid and other ancient writers, seven sons and seven daughters. This is the most commonly received opinion, though Homer ('Il.' xxiv. 602, &c.) and others give the numbers variously. The pride of Niobe at having this numerous progeny was so great that she is said in ancient story to have insulted Latona, the mother of Apollo and Diana, by refusing to offer at the altars raised in her honour, declaring that she had a better claim to worship and sacrifices than one who was the mother of only two children. Latona, indignant at this insolence and presumption, called upon her children to revenge her, and punish the arrogance of Niobe. Apollo and Diana heard the prayer, and obeyed the entreaty of their outraged parent. All the sons of Niobe fell under the arrows of Apollo, while the daughters in like manner met their death from the hands of Diana. Chloris alone escaped the common fate. She was the wife of Neleus, king of Pylos. This terrible judgment of the gods so affected the now heart-stricken and humiliated Niobe, that she was changed by her excessive grief into stone on Mount Sipylus in Lydia. Pausanias says (i. 21, 3) that the rock on Sipylus, which went by the name of Niobe, and which he had visited, "was merely a rock and a precipice when one came close up to it, and bore no resemblance at all to a woman; but at a distance you might imagine it to be a woman weeping with downcast countenance."

The fable of Niobe and her children has afforded a subject for art, which has been finely treated by one of the greatest ancient masters of sculpture. It consists of a series, rather than a group, of figures of both sexes, in all the disorder and agony of expected or present suffering; while one, the mother, the hapless Niobe, in the most affecting attitude of supplication, and with an expression of deep grief, her eyes turned upwards, implores the justly offended gods to moderate their anger and spare her offspring, one of whom, the youngest girl, she strains fondly to her bosom. It is difficult by description to do justice to the various excellence exhibited in this admirable work. Its great merit is independent of fine execution, in which it is inferior as a whole to many other well-known productions of the Greeks. Its excellence consists in the finer qualities of sentiment, as expression, grace, propriety, and variety of action, with that unity of effect by which the scene is brought dramatically and at the same time truly before the spectator, and a story of the most affecting interest told in language that cannot be mistaken. The arrangement of the composition is supposed to have been adapted to a tympanum or pediment. The figure of Niobe, of colossal dimensions compared with the other figures, which are life size, forms, with her youngest daughter pressed to her, the centre; while the rest of the sons and daughters are ranged in various ways on each side, some exhibiting expression of fear, others agonised with pain, others in grief, while one of the sons lies dead or dying, and stretched upon the ground. All are graceful, and some of the figures possess also great beauty, and the action and expression of many of the heads offer admirable examples for study to the artist. The whole attitude and expression of Niobe herself may truly be called sublime.

The colossal scale of the principal figure has justly been objected to as a fault. The artist doubtless had two purposes in view when he

ventured on this deviation from truth. The first was the necessity which he felt of giving a superior height and volume to the apex and key, as it were, of his composition; and next perhaps the desire he had to concentrate the interest in his chief figure by forcing it thus upon the attention. But although we should hesitate before taking any exception to the practice of the great leaders and masters of art, yet, generally speaking, any departure from the truth of nature—the real canon of excellence when rightly studied—is so far from being commendable or admissible, that, where it has been indulged in by the ancients with the view of gaining greater effect and energy, it may usually be considered rather as evidence of their inability to work out their idea with the authorised means, than as a practice to be admired or imitated; and it may always be argued that they would have been so much the more entitled to our admiration if they had produced their works within those limitations which nature dictates. The productions which exhibit these faults, for they must be accounted so, will be found to be worthy of the high estimation in which they are held for other properties, and rather in spite of than because of the licence which their authors have allowed themselves.

The execution of this interesting monument of Greek art is attributed by some to Scopas, a native of Paros, who lived about 300 years before the Christian era; while others think it is the production of Praxiteles. Pliny says it was a question which of the two was the author of it. The group was in the temple of Apollo Sosianus at Rome. (Plin., 'Hist. Nat.', xxxvi.; Sillig., 'Catal. Artificum,' in verb.)

Flaminio Vacca says the group of Niobe and her children was found at Rome, but outside the walls, near S. Giovanni; but the learned antiquary Fea denies this, and says it was found near the Villa Altieri. The well known statues of the "Boxers" were discovered at the same place, and it has been supposed by some that they formed part of the group; the fable being that some of the children of Niobe were slain while thus exercising. (Winckelman, 'Sur l'Allegorie,' pref.)

All the above statues are in marble, and are now at Florence in the gallery of the grand-duke of Tuscany; but many of them are thought to be copies only, from originals now lost. There is in England a head of Niobe, which is engraved in the 'Select Specimens of Sculpture,' published by the Society of Dilettanti (vol. i., pl. 35) similar in action and expression, but preferable, for its style and execution, to that of the Florence statue; and as there are known repetitions of some of the other figures, it is not improbable that the principal and most interesting of the series may also have been frequently copied, and that the figure in the grand-ducal collection, though an ancient work, may come under this class.

The subject of Niobe and her children was a favourite one also with the poets of antiquity. Besides the beautiful story in Ovid ('Metam.', vi. 146), there are numerous epigrams in the Greek Anthology, several of which have great merit, and appear to be descriptive either of the group of figures which still exists, or of some similar group. See particularly that beginning—

Τανταλί παῖ Νιόβα, κλύ' ἐμὸν φάτιν ἄγγελον ἔτας.

(For further information and references as to the group of Niobe, see Thiersch, *Ueber die Epochen der Bildenden Kunst*, &c. pp. 368, &c.; and Mr. Cockerell's restoration of them as they probably appeared in the pediment of the temple of Apollo, in the *Galleria di Firenze*, ii., tav. 76.)

NIOBIUM (Nb), a metal lately discovered in the tantalate of Bavaria by H. Rose. When perchloride of niobium is submitted to the action of dry ammonia it becomes yellow, with considerable evolution of heat, and when this is heated it becomes black, with the disengagement of hydrochlorate of ammonia. On washing it with water, to free it entirely from this salt, the water passes clear as long as it contains any of it; but when the metal is nearly pure the water becomes turbid. When niobium is heated in the air it burns with the evolution of light, and becomes white niobic acid. Nitric acid and aqua regia, even when boiling, do not act upon niobium; but it is acted upon by a mixture of nitric and hydrofluoric acids, and a red vapour is formed during the action.

Niobic acid readily combines with the alkalis; and when fused with alkaline carbonates, carbonic acid is expelled. These compounds are soluble in water. Acids precipitate niobic acid from these salts.

Infusion of galls, added to a solution of niobate of soda, produces a deep orange-yellow precipitate. Ferrocyanide of potassium produces a similar effect, and the red ferrocyanide gives a deep yellow precipitate. When a plate of zinc is put into a solution of niobate of soda, a blue precipitate is formed, which in course of time becomes brown.

NISAN (נִסָּן) is the seventh month of the Jewish civil year. It was anciently the first month of the year, as appears from the Book of Esther, iii. 7. The name occurs twice in the Bible, once in Esther, as just mentioned, and again in Nehem. ii. 1. It is also found twice in the Apocrypha; in Esdras v. 6, and in Esther xi. 2: in the last case it is written Nison. In the inscription of Palmyra the month is written exactly as in the Hebrew Bible, and Josephus also writes Νισάν. In the manuscripts containing the Calendar of Heliopolis, the name is read variously Νεισαν, Νυσσαν, or Νυσσαν, and even Νιρα; but the manuscript containing the last two forms is said to be damaged. Renfey derives the name from Zend words signifying "new day;" but these words do not actually occur in Zend, as Renfey admits, though

they are very probable forms. We would rather derive it from the Zend *nava sareda*, new year; a name almost certainly in use among the Persians, for we find the Armenians, who adopted the Persian calendar, using to this day the name of Navasardi for their first month; the Zend *rd*, as shown by Opperk, becomes *l* in Persian, and the word sarda has now become actually *sal*. [See also ELUL.] The final *l* often becomes *n* in Semitic dialects, and the few Samaritans who are now remaining say Israen for Israel, and gaman for gimel. Nisan varies with the lunar calendar from March to April: in this year (1860) it begins on the 24th of March and ends on the 22nd of April. The feast of the Passover begins on the 15th day of the month. A fast is set down by some authorities for the 10th of the month, in memory of the death of Miriam, and another on the 26th for the death of Joshua; but they do not appear to be generally observed.

There are thirty days in Nisan, and the month must not begin on either Monday, Wednesday, or Friday.

NISI. [RULE IN LAW.]

NISI PRIUS. This phrase in English law is derived from an ancient writ in which the words occur. Previously to the time of Edward I., trials by assizes or juries could only take place in the *curia regis*, wherever the king happened to be resident, or before the justices in eyre on their septennial circuits through the several counties of England. But by the stat. 13 Edw. I., cap. 30 (forming a part of that series of laws commonly called the Statute of Westminster 2), the judges were directed to take certain assizes, and also to try certain inquests, by juries in every county not oftener than three times in every year; but the statute required that the day and place in the county in which an issue was to be tried by the judges should be mentioned in the judicial writ which assembled the jury. Accordingly the *Venire facias*, or writ for summoning the jury (commanding the sheriff to bring them to Westminster to try the particular cause in which issue had been joined), contained a proviso, thus:—"We command you that you cause to come before our justices at Westminster on the morrow of All Souls, twelve lawful men, who, &c., unless before (nisi prius) that day, A.B. and C.D., our justices assigned for that purpose, shall come to your county to take the assizes there." It was, in practice, always arranged that the day for the return of the jury at Westminster should be more distant than the day for taking the assizes in the county; and consequently the exception in the writ invariably took effect by the justices of assize coming into the county and trying the cause before the sheriff was called upon to obey it by returning the jury to Westminster. [ASSIZE.] From this clause in the *Venire facias*, the phrase Nisi Prius came to be adopted as a general term descriptive of the large class of judicial business which is transacted before judges of the superior courts at the assizes. Thus the judges of assize are, when sitting alone to try causes, said to be sitting at Nisi Prius; and the law relating to the various matters which arise before them is, somewhat indefinitely, called the Law of Nisi Prius. It is erroneously stated in our text-books that the judges on circuit act under a commission of Nisi Prius. This is a common error, derived however from high authority, as it is so stated by Bacon in his 'Essay on the use of the Law.' There is in truth no such commission known to our law, the authority of the justices at Nisi Prius being incidentally annexed to the commissions of assize. In Middlesex the judges sit at Nisi Prius by statute 18 Eliz., c. 12; in London by virtue of immemorial usage.

NITRATE. [NITROUS ACID.]

NITRATES. [NITROGEN.]

NITRIC ACID. [NITROGEN.]

NITRIC ACID, Medical Properties of. This acid in a concentrated form acts as a violent corrosive poison, and is therefore never used in an undiluted state for internal administration, but is sometimes applied externally, when the object is to effect the speedy destruction of any part. Nitric acid however, from its frequent employment in the arts, is often the cause of accidental, rarely of intentional, poisoning, and it surpasses all the other mineral acids in the rapidity of its action, and in the consequent necessity for prompt and judicious treatment. It may be determined to have been the poisoning agent by its causing the parts which it has touched to be at first white, but soon after of a yellowish colour, which cannot be removed, like the stain of iodine, by adding caustic potass, but on the contrary becomes orange on the addition of an alkali or soap. (Pereira.) When it has been taken internally, the lining membrane of the mouth also peels off in a state resembling parchment. The most appropriate antidotes are such substances as combine with and neutralise the acid: chalk or magnesia, made into paste with water—or, if these are not at hand, the plaster of the apartment, bruised down and drank—will answer best. "While these are preparing, the acid should be diluted by the free use of any mild fluid, milk or oleaginous matter being preferred. The carbonates of the alkalis are by no means eligible antidotes, as the resulting compounds themselves possess corrosive properties." (Christison.) A solution of soap may be administered, though some object to it from the presence of the alkali in it, but apparently without sufficient ground. If recovery should take place, the individual long suffers from indigestion, and is almost always constipated.

In an undiluted form, nitric acid is a most valuable application to sloughing phagedenic ulcers; also for destroying warts; for the destruction of hæmorrhoidal tumours (see observations on this subject

by Henry Lee, London, 1848); or causing vesication over the stomach in Asiatic cholera, or for dropping into a carious tooth to relieve tooth-ache. For all other purposes it is very largely diluted.

In its action on the system it differs from other acids, inasmuch as it does not produce the cooling and thirst-allaying effect which they do, but on the contrary causes a feeling of warmth in the stomach, with thirst and increase of appetite. The use of it continued for some time gives rise to general effects; an excitement is felt through the whole system; the pulse becomes quick, the exhalation great; and an increased secretion from the salivary glands, mucous membranes, the liver, and kidneys is manifest. Perseverance in the use of this agent however at last produces many bad consequences; and in persons much disposed to bleeding from the lungs, it almost invariably causes such bleeding to occur, as well as heat in the chest and obstinate cough. Very largely diluted, it furnishes one of the best drinks in fevers accompanied with great prostration of strength.

It is also a very excellent tonic in many cases, and seems to form the best substitute for the bile where that secretion is scanty. That it greatly augments the secretion of bile, the nature of the evacuations abundantly proves. Hence it differs from almost all other tonics in not causing constipation, but rather the contrary. In calculous diseases of the phosphatic diathesis it has been used with great benefit; and also, very largely diluted, it has been injected into the bladder as a direct solvent. [LITHONTHRIPTICS.] In the treatment of scrofula it is a most valuable remedy, but its use must be every now and then suspended, owing to the effects which it produces on the stomach. During its use, care must be taken to protect the teeth, by instantly rinsing the mouth.

It has been regarded as a substitute for mercury in some cases, especially as it promotes the secretion of saliva. It ought never to be given at the same time as mercury, nor even soon after a dose of any mercurial preparation, since a poisonous nitrate of mercury may be formed in the stomach. Lastly, nitric acid increases the efficacy of many other medicines, such as ammoniacum, cusparia, and opium.

Nitric acid in the form of vapour was formerly employed as a disinfecting agent, but it is now almost disused. The vapour must be carefully avoided, as the inhalation is very deleterious.

Nitric acid in combination with hydrochloric acid, added to a large quantity of water, has been used as a bath in chronic diseases of the liver, particularly in India, but it does not seem entitled to much credit.

Nitro-hydrochloric acid is a most valuable tonic in some forms of indigestion and debility, in combination with bitters.

NITRIC OXIDE. [NITROGEN.]

NITRIDES. [NITROGEN.]

NITRIFICATION. When organic matters containing nitrogen undergo decay in the presence of alkaline substances, such as lime or potash or their carbonates, a considerable quantity of the nitrogen becomes converted into a nitrate of the base at the expense of atmospheric oxygen. When potash is the base present, the matters generally become coated with an encrustation of crystalline nitrate of potash, commonly called nitre: hence the name of the process. Much of the nitre of commerce is thus made.

NITRILES, a generic name applied in chemistry to compounds which are obtained by removing four equivalents of water from the ammonia salts of certain acids; thus acetonitrile, or the nitrile of acetic acid, is produced as follows:—

The nitriles are now known to be identical with the cyanides of the positive radicals; thus acetonitrile is cyanide of methyl:—

NITRITES. [NITROGEN.]

NITRO. NITR. Prefixes used in chemistry to denote the presence of nitrous acid (NO_2) as a substitute for hydrogen, in the body to which they are attached. Thus nitro-benzole ($\text{C}_{12}\text{H}_5(\text{NO}_2)$), nitraniline ($\text{NC}_{12}\text{H}_5(\text{NO}_2)$). Such compounds when not mentioned under their respective names, will generally be found described under the name of the body to which the prefix is added.

NITROBENZIDE. A nearly obsolete name synonymous with nitrobenzole. [BENZOLE, nitrobenzole.]

NITRO-BENZOIC ACID. [BENZOIC ACID.]

NITRO-CHLOROBENZOIC ACID. [BENZOIC ACID.]

NITROCOCCUSIC ACID. ($\text{C}_{16}\text{H}_5(\text{NO}_2)_3\text{O}_6 + 2\text{Aq.}$) Derived from carminic acid [CARMINE], by the action of strong nitric acid at a boiling temperature. Oxalic acid is formed at the same time, but may be separated by precipitation with nitrate of lead, nitrococcus acid not being thrown down by that reagent. On evaporating the filtrate from the oxalate of lead precipitate, nitrococcus acid crystallises out, and may be obtained perfectly pure by two or three recrystallisations.

Nitrococcus acid occurs in yellow rhombic plates. It is soluble in water, alcohol, or ether, and deflagrates violently on being heated. Its solution stains the skin of a yellow colour; dissolves iron and zinc,

becoming dark-coloured; and is decomposed by sulphide of ammonium with separation of sulphur and formation of a new acid not yet examined. The nitrococcusates have the general formula ($\text{C}_{16}\text{H}_5\text{M}_2(\text{NO}_2)_3\text{O}_6 + x\text{Aq.}$); those of ammonia, potash, baryta, copper, and silver are crystalline and soluble in water.

NITRO-ERYTHROMANNITE. [ERYTHRIC ACID.]

NITROGEN. This gas constitutes seventy-nine hundredths, or about four-fifths, of the atmosphere. Its name is derived from the Greek words *νιτρον*, nitre, and *γεννᾶω*, I produce. It was formerly called azote, or azotic gas, from a privative, and *ζωή*, life, indicating its inability to support respiration. It was first discovered by Dr. Rutherford of Edinburgh; he gave it the name of mephitic air, and described it in his 'De Aëre Mephitico,' published in 1772. Dr. Priestley procured it about the same period, and described several of its qualities in the 'Philosophical Transactions' for 1772; he afterwards called it phlogisticated air.

This gas may be obtained by several processes. Dr. Rutherford separated it from the oxygen gas, with which it forms atmospheric air, by repeatedly breathing the same portion of atmospheric air, and agitating it afterwards with a solution of caustic alkali; this absorbed the carbonic acid formed during respiration, and left the nitrogen gas unacted upon.

Dr. Priestley procured nitrogen gas by exposing a given volume of atmospheric air to a mixture of sulphur and iron filings; by this the oxygen was absorbed, and the nitrogen gas left. He also prepared it by some other means.

The readiest method of obtaining this gas is by the following process: Put a small piece of phosphorus in a little cup fixed to a cork floating on water, and set fire to it; while burning, hold inverted over it and dipping a little into the water, a glass jar or wide-mouthed bottle containing atmospheric air. During combustion the phosphorus unites with the oxygen of the air to form phosphoric acid, but having no affinity for the nitrogen gas, that remains nearly in a pure state, when it has either stood over the water or been agitated with that liquid, until all the white vapour of phosphoric acid has disappeared.

Nitrogen may also be separated from atmospheric air by the slow combustion, as it is termed, of phosphorus; that is, by merely exposing a stick of phosphorus, supported by a wire, in a bottle of air inverted over water.

By the exposure of moistened iron filings or iron borings to air in a bottle inverted over water; the metal oxidises, and the nitrogen gas is left: this acts even more slowly than the phosphorus in the above experiment.

By the agitation of mercury and lead in a corked bottle for a few minutes a black powder is formed, which is probably a mixture of an oxide of lead with finely-divided mercury; nitrogen gas is left.

The passing of atmospheric air over iron or, better, copper borings, heated to redness in a tube, is a useful method of preparing nitrogen when required on the large scale, but the process does not yield it in a perfectly pure state.

By exploding a mixture of 100 volumes of air and 42 of hydrogen, water is formed, and about 80 volumes of nearly pure nitrogen gas left.

Finally, nitrogen, when required absolutely pure, is best prepared by heating a mixture of chloride of ammonium and slightly alkaline nitrite of potash [NITROUS ACID], the nitrite of ammonia thus formed being split up according to the following equation:—

To free the gas from all traces of ammonia, it should be passed through a bottle containing dilute sulphuric acid.

Nitrogen is transparent, colourless, inodorous, and insipid. Its specific gravity is 0.9713; 100 cubic inches of it weighing 30.119 grains at 60° Fahr., the barometer marking 30 inches. Its refractive power, compared with air as unity, is 1.020; its specific heat, according to Berzelius, being 1.0247.

Nitrogen is generally considered as an electro-positive element, and in voltaic combinations is attracted to or elicited from the negative surface. Mr. Faraday has, however, found that, according to the nature of the substance decomposed, nitrogen may appear at either pole; but he concludes, that when it is evolved at the negative one it is a primary result, and when at the positive a secondary one.

Water dissolves but a very small quantity of this gas: according to Dr. Henry, 100 cubic inches take up only 1.47 cubic inches of the gas; Dr. Dalton states it to be 2.5, and Saussure 4.1 cubic inches. It is fatal to animals when respired by itself, as implied by the term azote; it extinguishes flame immediately; no degree of cold and pressure to which this gas has been subjected has condensed it to a fluid form.

Nitrogen resembles all other elementary bodies in being destitute of acid or alkaline powers; its affinity for substances, both elementary and compound, appears to be extremely weak, there being very few with which it combines by mere mixture, or by the action of heat under common circumstances. By electricity, however, or by the intense heat which the electric discharge excites, it may be made to combine with oxygen, and the result is nitric acid. The experiment was first made by Dr. Priestley; but the true nature of the action,

and the result of it, were ascertained by Mr. Cavendish. [NITRIC ACID.]

Although the properties of nitrogen are rather of a negative than a positive description, and although its affinities are weak, yet it enters into the composition of a great number of important compounds.

With hydrogen it constitutes the alkali AMMONIA, already described; with chlorine and iodine it gives rise to detonating compounds; with carbon it forms CYANOGEN; and with phosphorus a phosphide: it also combines with some of the metals forming *nitrides*, but they are all very unstable. It enters into the composition of most animal matters except fat; is seldom a constituent of the vegetable acids, but invariably forms a part of the vegetable alkalies.

Although nitrogen itself is fatal to animals, yet it is a most important constituent of the air, serving to moderate the action of oxygen during combustion, and the too great excitement which that gas respired unmixed would produce on the animal system. It appears also from the experiments of Majendie that animals cannot live on food that contains no nitrogen.

The equivalent of nitrogen is 14; combining volume, 2.

Oxides of nitrogen.—The compounds of nitrogen with oxygen are five; their names and formulæ are:—

1. Protoxide of nitrogen	NO
2. Binoxide of nitrogen	NO ₂
3. Nitrous acid	NO ₃
4. Peroxide of nitrogen	NO ₄
5. Nitric acid	NO ₅

1. *Protoxide of nitrogen, nitrous oxide, or laughing gas.* (NO.) This compound was first obtained by Dr. Priestley, who called it dephlogisticated nitrous air: he procured it by exposing binoxide of nitrogen to the action of iron, which deprived it of a portion of its oxygen, and reduced it to the state of protoxide of nitrogen. The properties of this gas were minutely examined by Davy. The best method of procuring it is to subject nitrate of ammonia to moderate heat in a retort; both the nitric acid and ammonia are decomposed, and their elementary oxygen, hydrogen, and nitrogen recombine in such proportions as to form water and nitrous oxide gas, thus:—

One ounce of the nitrate furnishes about one hundred cubic inches of gas.

Protoxide of nitrogen is colourless and transparent, its smell is peculiar but rather agreeable, and its taste is sweet: 100 cubic inches weigh about 47 grains, and its specific gravity is 1.527. Water absorbs about an equal bulk of this gas, but on being heated, gives it back unchanged. It has no action upon uncombined oxygen, in which it differs remarkably from the binoxide. It is composed of one volume of oxygen and two volumes of nitrogen condensed by combination into two volumes.

Protoxide of nitrogen supports combustion, and a taper, ignited phosphorus, sulphur, and charcoal burn vividly in it; at a red heat it is resolved into its constituent gases in the proportions stated. When a mixture of one volume of this gas and one of hydrogen is fired by the electric spark, water is produced, and one volume of nitrogen remains: this shows that it must contain half a volume of oxygen, that amount being required to form water with the one volume of hydrogen.

This gas was supposed to be irrespirable, until Davy, in his 'Researches on Nitrous Oxide,' showed that it might be breathed for a short time with impunity. When required for inhalation it should be prepared from pure nitrate of ammonia, should be collected over water, and allowed to stand in contact with that liquid for a few hours. It is most conveniently taken into the lungs from an india-rubber bag, furnished with an ivory mouth piece, the passage into the bag being free and of considerable size. The effects it produces vary considerably with different individuals. After a few inspirations the body of the person usually commences to describe a kind of rolling movement, similar to that which frequently occurs under the influence of intoxication, the bag is clutched more earnestly, and inspirations taken more zealously, until in from one to three minutes the subject either suddenly rushes among the bystanders in a state of enthusiastic pugilism, or shrieks and is convulsed with laughter, or, in a condition of unstable equilibrium, stands blinking at nothing, with a grinning, semi-idiotic gaze. Protoxide of nitrogen has well earned for itself the name of *laughing gas*, not so much perhaps from the effects it produces on the patient, as from the roars of laughter elicited from those who witness its inhalation.

Protoxide of nitrogen may be obtained in the liquid state by subjecting it to a pressure of about forty atmospheres. Once compressed it may be preserved in a reservoir for two or three days, but soon begins to attack the brass or copper fittings. On opening the stopcock the first portions of the liquid freeze into a solid mass, resembling snow; but it afterwards flows freely, and being received into an open glass remains fluid for nearly an hour. During the whole time, however, it is slowly evolving gas.

Liquid protoxide of nitrogen is a colourless, mobile, and perfectly transparent fluid. A drop let fall upon the skin rapidly evaporates, producing a painful burn. Mixed with bisulphide of carbon and exposed to evaporation in vacuo, a reduction of temperature ensues to probably 252° below the freezing point of water, at all events to a much lower point than has hitherto been obtained by any other means. Metals dropped into liquid protoxide of nitrogen produce a noise as though red-hot iron were immersed in water. Mercury causes the same noise, instantly freezes and affords a hard brittle mass, of the appearance of silver. Potassium floats upon the liquid, but experiences no change, and the same is the case with charcoal, sulphur, phosphorus, and iodine: strong sulphuric and nitric acids freeze immediately; ether and alcohol merely mix with the liquid; but water is instantly frozen with an almost explosively sudden elimination of gas.

2. *Binoxide of nitrogen, deutoxide of azote, or nitric oxide* (NO₂). Although this gaseous body had been obtained by Hales, yet it is to Dr. Priestley that we owe the first distinct account of the method of procuring it and a description of its properties. When certain metals such as mercury, or better copper in the state of borings, are put into dilute nitric acid, they are dissolved. During their solution, owing to the partial decomposition of a proportion of the nitric acid and the absorption of its oxygen by the metal, gaseous binoxide of nitrogen is plentifully formed and evolved. It has the following properties:—it is gaseous, or permanently elastic, not having been hitherto condensed into a liquid by any degree of cold or pressure to which it has been subjected. It is colourless, and probably tasteless and inodorous; but when an attempt is made to inhale it, it excites violent spasm of the glottis by meeting and combining with the oxygen of the air, which converts it into nitrous acid gas, a very different compound. Its specific gravity is 1.039; 100 cubic inches weighing rather more than 32 grains. Water at 60° dissolves about 11 per cent. It has no action on litmus paper, nor does it in any way exhibit the properties of an acid; but as already noticed, nitrous acid is formed as soon as it comes into contact with oxygen, and then it reddens litmus paper; this property distinguishes it from all other gases whatever, and renders it a test of the presence of uncombined oxygen: this was the gas first employed by Dr. Priestley in his eudiometrical researches. It supports combustion, if the temperature of the combustible be sufficient to decompose it into oxygen and protoxide of nitrogen, thus, charcoal and phosphorus immersed in it when they are in vivid combustion, burn splendidly, but a burning candle is extinguished: sulphur also, if only sluggishly burning, is extinguished; but when its temperature is raised to near the boiling point it burns readily. It is decomposed when passed through red-hot tubes; and the same effect is produced by a succession of electric sparks. It is also decomposed when exposed to zinc or iron, which take away half the oxygen and convert it into protoxide of nitrogen. It is soluble in a solution of protosulphate of iron; the solution has a deep green or brownish colour, and has been used in eudiometry to ascertain the proportion of oxygen in gaseous mixtures; but it cannot be advantageously so employed.

It is composed by volume, of—

Fifty cubic inches of oxygen gas =	17.20 grains
Fifty cubic inches of nitrogen gas =	15.05 „
	32.25 grains.

3. *Nitrous acid, hyponitrous acid* (NO₃), was discovered by Gay-Lussac, who obtained it by adding excess of binoxide of nitrogen to oxygen gas, confined in a glass tube over mercury, containing a concentrated solution of potash; under these circumstances 50 volumes of oxygen unite with 200 volumes of binoxide of nitrogen, forming nitrous acid which unites with the alkali. This acid may also be obtained by long exposure of binoxide of nitrogen gas to solution of potash, or by exposing to intense cold a mixture of 50 volumes of oxygen gas with 200 volumes of binoxide of nitrogen gas. By this operation the acid is obtained in a liquid state and possesses the following properties:—

At common temperatures it is green or blue, but at 0° it is colourless; it is very volatile, so that when exposed to the air, it is rapidly converted into an orange vapour, the density of which is stated to be 1.72. When water is added, the acid is decomposed and converted into nitric acid and nitric oxide, the latter escaping with effervescence. This acid does not readily combine with bases to form salts, being on their admixture converted into nitric acid and binoxide of nitrogen. Nitrites may however be formed by moderately heating certain nitrates, the acid of which then loses two equivalents of oxygen, nitrous acid remaining in combination with the base. Nitrite of potash is thus formed, the nitrate being heated until the oxygen evolved contains nitrogen. Solution of nitrite of ammonia, a convenient source of pure nitrogen, is most advantageously formed in the following way: one part of starch is gently heated with ten parts of nitric acid, and the nitrous acid gas produced passed into solution of potash, of sp. gr. 1.38, until the solution acquires an acid reaction; a little caustic potash is then added, so as to render it distinctly alkaline, and the resulting liquid when required for the preparation of nitrogen is mixed with three times its bulk of a saturated solution of chloride of ammonium, and the whole gently heated; the nitrite of ammonia formed in this

process is decomposed by the heat as described above. Nitrite of lead may be formed by heating metallic lead in a solution of the nitrate of that metal. Nitrate of silver is thrown down as a white precipitate on adding together solutions of nitrite of potash and nitrate of silver; it is soluble in hot water and crystallises out on cooling.

4. *Peroxide of nitrogen* (NO_2), was long supposed to possess acid properties, and hence was called *hyponitric acid* and formerly *nitrous acid*. It may be obtained in the gaseous, liquid, or solid form.

Gaseous peroxide of nitrogen is formed on mixing binoxide of nitrogen with half its volume of oxygen in an exhausted receiver; immediate combination and condensation occur; heat is evolved; a red gas is formed, which is the peroxide of nitrogen, and when this coloured gas is subjected to a temperature of 0° , it becomes liquid, and sometimes solid. When also nitrate of lead is heated in a retort, it is decomposed, and red vapour of peroxide of nitrogen is emitted, which is condensed to the liquid state by being subjected to a freezing mixture. Towards the latter part of the operation the compound comes over in the anhydrous state, and may be obtained in crystals in a fresh, well-dried and cooled, receiver. The slightest trace of moisture prevents the formation of the crystals. Liquid peroxide of nitrogen is of a pale colour, but becomes darker when heated; it emits a very strong disagreeable odour, and at a very moderate rise of temperature reassumes the gaseous form. It is decomposed by water with strong effervescence, being immediately separated into binoxide of nitrogen, which is evolved, and nitric acid, which remains in solution.

Nitric acid (NO_3). *Azotic acid*.—This important acid may be formed by the direct combination of oxygen with nitrogen, or with any of the other lower oxides of nitrogen; by decomposition of ammonia in presence of oxygen; by the passage of electric sparks (for example, lightning) through atmospheric air, or by the EREMAUCAUSIS of organic bodies that contain nitrogen. In combination with bases nitric acid is met with in nature in great abundance: it is rare to meet with a specimen of rain-water that does not contain traces of nitrate of ammonia; most varieties of chalk contain a small quantity of nitrate of lime, and in many tropical climates, especially some parts of India and Peru, nitrates of potash and soda effloresce from the ground during the dry seasons of the year. The production of these nitrates is no doubt due to one, or a combination, of the causes already alluded to so far as the nitric is concerned, while the several bases are always at hand in the soil in the state of carbonates or other salts decomposable by nitric acid. Native nitrate of potash constitutes the crude *nitre*, or *saltpetre* of commerce, and is the substance whence we derive nitric acid itself, and most of the other nitrates.

Ordinary liquid nitric acid was known so early as the 7th century; Raymond Lully obtained it from nitre; Geber termed it *solutive water*, and Glauber manufactured it by the agency of sulphuric acid, in precisely the manner adopted at the present day. Cavendish, however, first made known its composition in 1785 [CAVENDISH, HENRY, in *BIOG. DIV.*], and our knowledge of it has since been perfected by Davy, Gay-Lussac, Thompson, and others. On the small scale, nitric acid is conveniently obtained by heating in a glass retort with a tolerably long neck, a mixture of equal weights of nitrate of potash and oil of vitriol; monohydrated nitric acid then distils over, and is readily condensed, while bisulphate of potash remains in the retort. The following equation represents the decomposition:—

On the large scale, nitrate of soda (Chili saltpetre) is used in the place of nitrate of potash, and the process is conducted in capacious iron cylinders, coated on the upper part of the inner surface with fire-clay, to prevent the action of the nitric fumes upon the metal. Manufacturers use the soda nitrate, because it is cheaper than the potash salt, contains nine per cent. more acid, and is decomposed at a lower temperature, thereby enabling a saving in fuel to be effected. Iron retorts are used in the place of glass or earthenware, because the salt left in them can be a neutral sulphate, instead of a bisulphate, thus admitting of the use of one-half the quantity of sulphuric acid that otherwise would be necessary. Neutral sulphate of potash or of soda is, however, exceedingly hard, and being but sparingly soluble in water, has to be detached from vessels containing it by the use of iron tools, a proceeding somewhat hazardous if those vessels are of glass or earthenware.

As obtained by the above process, nitric acid is a colourless, transparent liquid, of sp. gr. 1.520. One hundred parts contain 85.72 of anhydrous nitric acid (NO_3), and hence its composition is expressed by the formula HO, NO_3 . It boils at 184° Fahr., and freezes at -40° . Exposed to the air it continues to fume very strongly until it has absorbed sufficient water to constitute it a terhydrate ($\text{HO, NO}_3 + 3 \text{Aq.}$): this is the condition of maximum stability of aqueous nitric acid; a weaker acid loses water on boiling until the state of terhydrate is reached, a stronger acid losing nitric acid under the same circumstances. Terhydrated nitric acid has a sp. gr. of 1.424, contains sixty per cent. of anhydrous acid, and boils at 250° Fahr. Nitric acid readily absorbs the lower gaseous oxides of nitrogen, forming a yellow, or even red, fuming liquid, known by the

name of *aqua fortis*. It also becomes of the same colour when any organic matter, such as a piece of straw or paper is allowed to fall into it; even mere exposure to sunlight will produce the same decomposition. The chief cause of the instability of nitric acid is the readiness with which it parts with a portion of oxygen; indeed, as an oxidising agent, it is in constant request by the chemist. Metals thrown into it are rapidly converted into oxides with evolution of binoxide of nitrogen and production of orange-red nitrous fumes, a reaction taken advantage of in testing for the presence of nitric acid; sometimes the binoxide of nitrogen is made to pass into solution of protosulphate of iron, in which it dissolves with formation of a black compound, a reaction that is even more delicate than that with the copper turnings; it is performed as follows. Into the liquid suspected to contain nitric acid, or a nitrate, a few crystals of protosulphate of iron are placed, and the whole is agitated for a minute or two to facilitate the solution of a little of the salt; strong sulphuric acid is now cautiously poured down the sides of the vessel, and being heavy flows on to the crystals at bottom, and at once gives rise to the black compound in question if a trace of nitric acid be present. The cause of the production of the compound is the oxidation of a part of the protosalt of iron to a persalt by the nitric acid, binoxide of nitrogen being evolved, and combining with the undecomposed protosulphate; the use of the sulphuric acid is to liberate nitric acid from combination, and to facilitate the formation of the persulphate of iron.

Nitric acid is one of the most corrosive substances known; it permanently stains the cuticle of a yellow colour, and in a similar way attacks wool, feathers, and all animal matters that contain albumen. Its strength is most readily ascertained by taking its specific gravity, and then consulting such a table as the following, an abridgement of one constructed by Dr. Ure:—

Specific gravity.	NO_3 in 100 parts by weight.	Specific gravity.	NO_3 in 100 parts by weight.
1.5000	79.700	1.2887	39.053
1.4940	77.303	1.2705	36.662
1.4850	74.918	1.2523	34.271
1.4760	72.527	1.2341	31.880
1.4670	70.136	1.2148	29.489
1.4570	67.745	1.1958	27.098
1.4460	65.354	1.1770	24.707
1.4346	62.963	1.1587	22.316

1.3056	41.444	1.0053	0.797

Anhydrous Nitric Acid (NO_3). This was first obtained in brilliant, colourless, transparent, prismatic crystals, by M. Deville. The method of operating consists in passing a slow current of perfectly dry chlorine gas over pure crystals of nitrate of silver heated in an oil bath, and connected with a receiver made cool by a freezing mixture. The decomposition that takes place is thus expressed,—

In order to ensure success a number of precautions must be observed, for which see M. Deville's paper ('*Ann. de Chimie*,' III, xxviii. 241).

Nitrates. Salts formed by the union of nitric acid with a base; the number of equivalents of each being usually equal, never containing more acid than base, but frequently more base than acid. They are nearly all decomposed when strongly heated, deflagrate when thrown on to ignited carbon, and are mostly soluble in water.

Hydrides of nitrogen. Nitrogen united with two equivalents of hydrogen forms the hypothetical substance *amidogen*, a body that united with metals and electro-positive radicals, forms AMIDES. Nitrogen with three equivalents of hydrogen forms AMMONIA, and with four equivalents the compound radical *ammonium*.

Phosphide of Nitrogen (N_2P). Dr. Pauli states ('*Ann. der Chem. u. Pharm.*,' ci. 41), that when an intimate mixture of pentasulphide of phosphorus and chloride of ammonium is distilled, a light powder of slightly yellow colour is obtained as a residue, which is phosphide of nitrogen. It is insoluble in water and nitric acid, and when melted with potash evolves ammonia.

Sulphide of Nitrogen (NS_3). A compound formed by the re-action of protochloride of sulphur, ammonia and water. It exists in two isomeric states; in the one it is of a light green colour, in the other it is yellow. It crystallises from solution in hot ether, is inodorous and has but little taste.

Iodides of Nitrogen. [IODINE, nitrogen and.]

Bromides of Nitrogen. [BROMINE, nitrogen and.]

Chloride of Nitrogen. [CHLORINE, nitrogen and.]

NITROHEMATIC ACID ($C_{12}H_5(NO_4)_2NO_2$) *Picramic Acid*. This acid was discovered by Wöhler. Its name is derived from *hæma* (*âma*), *blood*, in allusion to the colour of its salts. It is prepared by mixing carbazotic or nitropicric acid with protosulphate of iron and digesting the mixture with hydrate of barytas and water. The protoxide of iron separated, becomes peroxide at the expense of the nitropicric acid, and a new acid is formed, which is the nitrohematic acid; it is separated by a tedious process from the baryta with which it combines as it is formed, and then has the following properties:—

It has the form of small brown crystalline grains, and scarcely any taste; when exposed to a moderate heat, it begins to liquefy and afterwards detonates without the evolution of light, but with the formation of cyanide of ammonium and the deposition of carbon, which burns without leaving any residue. It is but slightly soluble in water, and the solution is yellow; it dissolves in nitric acid.

With bases it forms peculiar salts, the solutions of which are of a deep blood red colour; but when dry, they are of a deep brown with a tint of green and a semimetallic lustre; the alkaline and earthy salts of this acid have a bitter taste, and when heated they detonate like gunpowder. The nitrohematate of ammonia has rather a crystalline appearance, and when heated it detonates with the evolution of light, and the formation of much cyanide of ammonium.

NITROHYDROCHLORIC ACID. *Nitromuriatic Acid. Aqua Regia*. A powerfully corrosive liquid, formed on mixing one measure of nitric acid with about three of hydrochloric acid. The alchemists called it aqua regia, from its property of dissolving gold, their "king of metals." It also attacks and dissolves platinum, and of course exerts the same action on all those metals that are soluble in nitric acid or hydrochloric acid separately; perchlorides in all cases being formed.

The solvent action of nitrohydrochloric acid has been shown by M. Gay-Lussac to be due to free chlorine. At least two other bodies are, however, produced simultaneously with the chlorine; they are rich in chlorine, but do not act upon metals; the one is chloronitric gas, the other chloronitrous gas.

Chloro-nitric Gas. (NO_2Cl_2). This gas constitutes the yellowish-red fumes that are evolved when nitrohydrochloric acid is gently heated. Passed through a tube surrounded by a freezing mixture it condenses to a cloudy lemon-coloured liquid. Its formation is attended with evolution of chlorine, as indicated by the following equation:—

Chloro-nitric gas is decomposed by water, chlorine and peroxide of nitrogen remaining in solution. It readily acts upon mercury but is not an acid, and does not combine with bases. It may be viewed as peroxide of nitrogen (NO_4) in which two equivalents of oxygen are replaced by two of chlorine.

Chloro-nitrous gas. (NO_2Cl). This gas comes off in greatest abundance towards the latter part of the operation of boiling nitrohydrochloric acid. It may also be obtained directly by allowing binoxide of nitrogen and chlorine to condense together in a vessel surrounded by a freezing mixture. Like chloronitric gas it is decomposed by water, and though not itself an acid may be viewed as nitrous acid (NO_3) in which an equivalent of oxygen is replaced by one of chlorine.

NITROLEUCIC ACID. [LEUCIN.]

NITROMURIATIC ACID. [NITRO-HYDROCHLORIC ACID.]

NITROSO-NAPHTHYLIN. [NAPHTHALIC GROUP.]

NITROSO-PHENYLIN ($C_{12}H_9N_2O_2$), an organic compound formed by the reducing action of zinc and hydrochloric acid upon binitrobenzole. It cannot be crystallised, but its alcoholic solution dries down to a brilliant black pellicle, which is nearly insoluble in water, but readily soluble in acids and alcohol. Its solution possesses a magnificent crimson colour.

NITROPICRIC ACID. [CARBAZOTIC ACID.]

NITROPRUSSIDES. [CYANOGEN.]

NITRO-QUERCITE. [MANNITE.]

NITRO-SULPHURIC ACID. [NITROGEN.]

NITRO-THEINE. [CAFFEINE.]

NITROUS ACID. [NITROGEN.]

NITROUS ETHER. [ETHYL.]

NITROUS GAS. [NITROGEN.]

NITROUS OXIDE GAS. [NITROGEN.]

NIZAM, the title of the sovereign of Hyderabad, derived from Nizam-ul-Mulk, who, after the death of Aurungzebe, obtained possession of the Mohammedan conquests in the Deccan, his name being assumed as a title by his successors in the sovereignty. After reigning 31 years, Nizam-ul-Mulk died at a very advanced age, in 1748. He was succeeded by his second son Nassir Jung, who was assassinated in 1750. His grandson Muzuffer Jung was then placed on the throne, and also assassinated in the year following. The third son of Nizam-ul-Mulk, Salabat Jung, then reigned until 1763, when he was put to death by his brother Nizam Ali, who thereupon took the reins of government, and held them till his death in 1803. His successor, Sekundar Jah, died in 1828, and was succeeded by Nazir-ud-Doulat, who died May 16, 1857. The present nizam is named Afzal-ul-Doulat. Under this prince the misgovernment attained so great a

height, and the debt to the British government became so large, that a territorial cession was effected; the revenue of the sequestered districts to be applied to the reduction of the debt and the maintenance of the military contingent.

The nizam is one of the native sovereigns with whom the East India Company made subsidiary treaties, and to which the British government by the cession of the Company's political power succeeded. The chief provisions contained in these treaties are—1st, protection by the British government against all enemies, foreign or domestic; 2nd, mutual co-operation in the event of hostilities with other powers; 3rd, the maintaining of a British force for the protection of the native state; 4th, the reception of a British resident, by whose counsel the native government is bound to abide as regards all public affairs, internal and external; and 5th, the abandonment on the part of the native prince of all political intercourse with other powers, except through the medium of the British government. Under this system the native princes are little more than viceroys, who administer the government according to the views of their superior; and in fact the British residents appointed under subsidiary treaties are not so much ambassadors as they are ministers. Connected closely with the presidency of Bombay, Hyderabad was not engaged in the mutiny of the native Indian troops in 1857-8, and consequently its political position remained unchanged.

NOBILITY. The slightest attention to the nature and the actual experience of man must convince every one that society has a tendency to inequality in the condition of the persons composing it. Take half a dozen youths, and place them in a society apart from all other persons of their kind; place them under no other condition than that each person shall enjoy what is his own in his own way; let the whole be at first as nearly on an equality as possible in respect of advantages which are not those of mere nature; and it is certain that at the end of fifty years they and their families will be in a state of great inequality, that some one among them will have attracted to himself more of the things which make life easy than any of the rest, and that there will be not only a difference but a very great difference between the most and the least successful of the party.

This arises from the inequality of the physical, the moral, and intellectual power of each, that is, of some one of those things which we say are the gifts of nature, combined with the introduction of principles and habits at a very early period of life, the things in short which make the man himself, independently of the adventitious advantages which are derived from the possession of things external to himself.

Thus bodily strength, adroitness, quickness of eye, capacity of bearing fatigue, steady industry, frugality, temperance, caution, foresight, aptness to seize opportunities, knowledge of the dispositions and characters of other men, will in any situation of life prove advantageous to those who possess them; and those who want them and are without an equivalent in some other valuable quality, can never expect to be in a situation equally favourable, when time has been allowed for the exercise of those faculties and for the production of their natural fruits.

When once a little advantage is gained, and another generation arises starting in life with the possession of the advantages which the talent or the good fortune of the father secured for it, if the same good physical, moral, or intellectual faculties are inherited, as may be the case, it is manifest that the elevation will become higher and the distinction greater. This will go on in an accelerating ratio, for the adventitious advantages operate as in a series of compound interest. On the other hand there may be a declension in another, till the lowest possible point of destitution has been reached. It seems that if once the principle of *property* is admitted, and every man is guaranteed in the possession of that which belongs to him, what we have described must necessarily take place. Society may by its institutions do something to restrain this tendency, or something which shall in its effects promote it; but society can never preclude it, except by measures which shall annihilate *property*. Whether such measures can be desirable, it is not our present business to discuss.

It is thus, we conceive, that the distinction of *nobiles* and *vulgares*, which we find in the earliest records of human society, must have originated.

Political consideration and political power will in some degree always follow wealth; and thus it has been that a larger share of influence in the direction of the affairs of a community has always fallen to the lot of those in whose hands, by their own exertions or those of their ancestors, a larger share of adventitious advantages had been accumulated than in the hands of others less able or less fortunate.

Nobility, in the earlier stages of civilisation, consisted, it is probable, in nothing more than the union of political power with wealth; but this would soon pass into that other state in which we in Europe now see it, where the particular political advantages were guaranteed to the family of him who once possessed himself of them, by which means there was created a new and very important distinction in society, and it became necessary that society should define who the persons were that were admitted by it to such desirable privileges. It was not now the mere possession of wealth and of that political power which will always more or less attend wealth which made a man *nobilis*; there must be some recognition of his admission into what constituted an order endowed with such privileges. Being once secured as an

hereditary possession, these privileges might fall to persons who had not wealth or the means of obtaining it, nor the influence and power which wealth brings with it.

When once society had thus established an order and regulated the means by which persons might be admitted into it, the desire would become general of admission to the privileges and advantages which belonged to it, in persons who had any pretensions to aspire to such advantages. It was then easily discovered that society had thus an unexpensive way opened to it of rewarding very eminent services. A community has not always manors and lands to give to the man who performs for it such services, nor are money pensions out of the taxes, continued from generation to generation, agreeable to those who contribute to the payment of them. But a society accustomed to such an order, and sensible of the benefits which attend the existence of such a state of things, willingly sees advanced into it men who are distinguished by very eminent talent, very eminent services, or very eminent virtues. It is a reward not given all at once, but through a long succession of years.

In the different countries of modern Europe there are nobles various in their titles and various in the privileges belonging to them. In England, Scotland, and Ireland, the heads of the families which are noble are either dukes, marquesses, earls, viscounts, or barons; all, except the last, originally names of office, originated in that state of society where the *nobles* were all men in actual political employment. To the heads only are political privileges given, the chief of which is, that the English peers have seats in the House of Lords, and consequently a voice in all projected changes of the law. But the junior members of the family are accounted noble, and have certain titles or honourable distinctions united with their names.

By the English constitution the privilege of placing a family in the rank of the nobility is vested solely in the sovereign. The phrase by which this is usually expressed is, that the sovereign is the fountain of honour. It is done by letters-patent declaring that such or such a person is created to the dignity, &c., to descend to the heirs male of his body, or in such manner as the crown may choose to direct.

The persons admitted into the order of nobility in England are now usually—1, Peers of Scotland or Ireland; 2, Persons distinguished for services in the army, navy, diplomacy, and for political services; 3, Younger branches of families already noble; 4, Persons of ancient wealth, with sometimes, though rarely, persons of large fortunes which have been recently acquired; and 5, Persons promoted to high judicial appointments, as the lord chancellor, the chief justice of the King's Bench, and others, usually called the law-lords.

New creations are essential to keep up the order, as extinction is perpetually taking place in a nobility such as the English, where few of the titles descend in any other way than to the male descendants of the person first ennobled.

There are modern communities, such as the United States of North America, in which there is no nobility in any respect resembling that of Europe. Wealth of course gives some influence and importance to the possessor, but it is also an object of jealousy, which must always be the case, more particularly in democratic constitutions. Office, so long as it is held, gives greater distinction than wealth; but office is only held for a short time, and wealth, although it may be acquired by an individual, is seldom transmitted to a single person, but is usually distributed in moderate or small portions among several persons. Thus it has been observed, that in the United States a family seldom maintains any great wealth or importance for more than two generations. Names which have been made illustrious by an individual are remembered only because of him who first elevated them to distinction, and the descendants of the wealthy lose with their wealth the remnant of that importance which their ancestor acquired. Thus one family of distinction after another sinks into obscurity, and its place is soon filled by a name before unknown.

NODAL POINTS AND LINES. Nodal points are those points in the length of a string extended between two fixed objects, or in a column of air confined at one or at each extremity, which, when the string or column is put in a state of vibration, are found to remain at rest; nodal lines are corresponding lines which exist on the surface of an elastic body, usually a plate, whose parts are in a state of vibration.

It is well known that if a string or a metallic cord be attached at its extremities to a board or plate, on causing it, when in a state of tension, to vibrate transversely, there may be distinguished, besides the principal sound, which is due to the length of the string, several others which have a greater degree of acuteness; these are called *harmonic sounds*, and they are conceived to result from some property of the extended string, by which, when in a state of vibration, it becomes a sort of moving axis, having on it points, at distances from one another equal to some aliquot part of the whole length of the string, at which points a contrariety in the directions of the vibrations of the particles keeps the latter in a state of rest. Such are called *nodal points*; and they may be conceived to form themselves in consequence of inequalities in the thickness or density of the string, or of different degrees of flexibility in its different parts. The string between every two such points is in the same condition as if it were attached at those points to fixed objects; its partial vibrations are consequently

such as are due to the distances between the points, and hence arise the secondary or harmonic sounds.

A string of considerable length, on being made to vibrate, will be found to have several such nodal points, and the curves which the intervals assume in consequence of the vibrations, though alternately on opposite sides of the axis of the string, are equal and similar to one another. The situations of the nodal points may be made evident by placing, at intervals, across the string, pieces of paper notched or bent in the form of an inverted V; those which are at the places of the nodes remaining at rest, while the others experience considerable agitations, or are thrown entirely off.

If a string, in a state of tension, have its extremities attached to a board or plate of metal, and be made in some part of its length, to pass over a bridge resting in the centre of the board or plate, the vibrations of the string, when a violin-bow is drawn across it, will be communicated to the plate; and if over the latter some light dust or powder such as fine sand or lycopodium be sifted, that dust will be agitated and made to arrange itself on lines at which the surface of the plate is in a state of rest: these are called *nodal lines*, and the figures which they form are called *Acoustic figures*. Again, if a glass rod be cemented at one end to the centre of a disk of the like material, and be excited by being rubbed, for example, with a wet cloth, so as to be put in a state of vibration longitudinally, those vibrations will be communicated to the disk, and light dust strewed over the latter when in a horizontal position will arrange itself in acoustic figures. Or, if a glass rod be connected at each extremity to a glass disk at right angles to its length, on exciting one of the disks by drawing a violin-bow across its edge, the vibrations of that disk will, by means of the rod, be communicated to the other; and if light dust be strewed over both it will arrange itself in figures: when the disks are equal and similar to one another, the figures are alike on both; otherwise they differ.

If a column of air in a cylindrical tube which is closed at either or at each end be acted upon by the force of the breath, for example, applied at an aperture in any part of its length; it will spontaneously divide itself into portions in which the particles are subject to equal and similar vibrations [ACOUSTICS; VIBRATION]: these portions are separated from one another by sectional areas in which the particles are at rest; the condensations, or rarefactions, of the air being, in those areas, greater than in any other parts of the tube in consequence of the particles moving in contrary directions, and with equal velocities towards, or from, them. Such areas are called *nodal sections*, and several may exist at the same time in the tube. Their existence is rendered evident by boring small holes in different parts of the sides of the tube and covering them with pieces of thin paper slightly adherent to the surface: at the nodal sections the papers will be scarcely affected, while, in the intervals, they will be greatly agitated.

If, in the side of a tube containing a column of vibrating air, any aperture exist by which that air is enabled to communicate with the atmosphere, the air in that section becomes in equilibrio with the latter, and, in that section, there is consequently neither condensation nor rarefaction: this section corresponds to the middle point between two nodes in a vibrating string.

Vibrations corresponding to those which are produced in strings or rods and in columns of air may be conceived to take place in any solid bodies or in any elastic fluids whatever be the figure of their mass: in such a mass there may be several places at which the vibrations are performed in contrary directions so as to produce nodal lines; and these, when they occur on the surface of the mass, may become sensible by means of light dust strewed over it. Some of the vibrations are found to take place parallel to the surface, and others perpendicular to it: the former being called *tangential*, and the latter *normal* vibrations. In one case the particles of dust glide upon the surface in directions which tend alternately towards and from the nodal lines (the movements in the former direction being always more rapid than those in the other) till they come to a state of rest on those lines; in the other case the particles alternately rise from and fall back upon the surface at the places where the latter is in a state of vibration; and, dispersing from those places, they become quiescent in the lines of no vibration.

Galileo was the first who observed (*Dialoghi delle Scienze Nuove*) that the vibrations of elastic plates might be rendered visible by covering the plates with fine sand; and he remarked that the sand became accumulated at the parts where the vibrating plate was in a state of rest: but this subject was extensively investigated by Dr. Chladni, of Wirtemberg, who first discovered the longitudinal vibrations of solid bodies; and, 1787, published, in a work entitled *Entdeckungen über die Theorie des Klanges*, an account of numerous experiments which he had made on the nature of the vibrations produced in plates of glass of different forms.

The plates with which such experiments may be performed should be of good window glass; and, if square, from 4 to 8 inches on each side; if circular, their diameters may be within the same limits: in making an experiment the plate must be held horizontally between a finger and thumb, or it may be fixed within the lips of a clamp screw or of suitable tongs, the points of contact being furnished with cork; and when it is required to prevent any particular part of the plate from vibrating, that part, if on the edge, may be pressed against

a fixed object, or, if at any part of the surface, one of the fingers of the hand may be pressed gently upon that part. The plate being in a horizontal position, it must be covered with a layer of fine dust such as lycopodium; and it may be put in a state of vibration by drawing a violin-bow across its edge: the dust will then arrange itself in figures which will vary with the form of the plate, the place at which the bow is applied, and that at which the plate is held. If, for example, a square plate be held at its centre, and the bow be applied near one of the angles, the dust will arrange itself in lines so as to divide the plate into four equal squares (No. 1). If the plate be held as before, and

the bow be applied at the middle of one of the sides, the vibrations will be such as to make the dust lie in the direction of the two diagonals (No. 2). Again, if the plate be held at A (No. 3) and the bow be applied at B, the dust will assume the positions of three lines parallel to one another: and if the plate be held at a point nearer the edge, the lines will become curves, as in No. 4.

If a circular plate, held at the centre, be pressed against a fixed object at any point on its circumference, and the bow be applied at 45° from that point, the lines will take the positions of two diameters at right angles to one another, one of them passing through the point at which the circumference touches the object. A greater number of radiating lines than four will be produced if the bow be drawn more rapidly and with less pressure against the edge of the plate than in the former case. If the centre of the circular plate be free, various curve lines will be assumed by the dust, according to the position of

the point which is held; and one of them is represented in No. 5. The figures represented in Nos. 6, 7, and 8, are selected from the great number which Chladni has obtained with glass plates of a circular, a polygonal, and a triangular form. Professor Wheatstone has calculated a large number of these acoustic figures by the principle of the superposition of small motions. (Phil. Trans.) Professor Faraday also describes (Phil. Trans., 1831) a number of interesting experiments on the subject.

Beautiful acoustic figures may also be obtained on the surface of mercury, water, spirit, &c., contained in a glass goblet, by drawing a violin-bow against its edge. This part of the subject is fully and carefully investigated in Mr. Tomlinson's 'Student's Manual of Natural Philosophy,' (1838). M. Felix Savart has observed, that if a rectangular plate of glass about 27 inches long, $\frac{2}{3}$ inch broad, and $\frac{1}{16}$ inch thick, be held horizontally between a finger and thumb at the middle of its opposite edges, and it be put in a state of longitudinal vibration, either by rubbing its under side, near one of the ends, with a wet cloth, or by striking it gently at one end, the dust on the upper surface will arrange itself in lines perpendicular to the length of the rod. It is remarkable, that if the plate be turned with its upper face downwards, being held as before, and vibrations be produced in like manner, the places of the nodal lines will be opposite to the middles of the intervals between the lines observed in the other position of the plate—a circumstance which proves that the motions of the particles in one-half of the thickness of the lamina of glass are directly contrary to those in the other half. A like effect has been observed when cylindrical rods of glass have been made to vibrate longitudinally; the lines of nodes then assuming a spiral form about the cylinder, and the curves consisting of portions which run alternately in contrary directions: the points of greatest and least inclination to the axis of the cylinder are at 90° from each other with respect to a line drawn on the surface parallel to the axis, and the effect is such as would arise if the cylinder were divided longitudinally into four quadrantal portions, having opposite qualities. The places of the nodes on that part of the rod which was uppermost were found, the rod being held in a horizontal position, by annular pieces of paper loosely encircling it.

In 1822, M. Savart read to the Académie des Sciences at Paris, an account of some curious experiments in which acoustic figures were produced in consequence of vibrations communicated through the air to elastic membranes. ('Brewster's Edinburgh Journal of Science,' vol. ii., p. 296.) A sheet of thin paper was slightly stretched over a glass vessel four or five inches in diameter, and on it was strewed light dust. A thin circular plate of glass, in a state of vibration, was then brought within a few inches of the paper, when the vibrations were communicated to the latter, and, the paper being of uniform thickness

and well stretched, the dust assumed figures which were perfectly regular. M. Savart, having rendered the glass plate immovable at opposite points on its circumference by holding it there between the thumb and a finger of each hand, placed the tip of another finger at a point on the surface, at a distance from the centre equal to about one-fifth of the diameter, and caused the plate to vibrate by drawing a violin-bow across its circumference. In these circumstances, on presenting the plate to the stretched paper, the following appearances were observed. The nodal figures on square paper were analogous to those formed on a square plate of glass or metal, and on circular plates their general character was circular. The circular lines were sometimes cut by diametrical lines which formed nodal points, or stars, and the number of these increased with the acuteness of the sound produced by the bow. When the plate of glass was parallel to the paper, the nodal lines were similar on both, as when two plates were connected with each other, by a rod fixed perpendicularly between them. When the plane of the glass plate was held vertically, the nodal lines on the paper became parallel to one another; and the figures on the paper changed as the glass plate was made to decline from the vertical position.

Some curious acoustic figures have been produced by M. Lissajoux by attaching a mirror to one of the prongs of a tuning fork, and allowing a ray of light to fall somewhat obliquely on the mirror. It is evident that under such circumstances the direction of the reflected ray will change with every vibration of the fork, and on allowing this reflected ray to fall on the screen, the vibrations of the fork become visible in the rapid motions of a point of light on the screen. In this way M. Lissajoux has rendered the vibratory movement of solid bodies visible and has made evident the optical composition of vibratory motions which take place in the same direction: he has also been able to compound two vibratory motions at right angles to each other; to show the accordance of two diapasens separated by a musical interval, and to give the means of fixing on a constant or invariable fundamental sound. The only fault of this highly suggestive method is that it does not leave a permanent trace of its indications.

NODE. The points of a planet's or comet's orbit in which it cuts the ecliptic, and the points in which the orbit of a satellite cuts that of its primary, are called the nodes of such planet, comet, or satellite. Generally, the point in which one orbit cuts a second is called the node of the first upon the second.

NOLLE PROSEQUI is a phrase used in proceedings at law to denote the withdrawal of the plaintiff from the further prosecution of his suit, and is derived from the words used in the formal entry of such withdrawal on the record, in which the party "acknowledges that he will not further prosecute" (*fatetur se ulterius nolle prosequi*), the consequence of which is that the defendant is entitled to his costs, under stat. 8 Eliz., c. 2, s. 2. In equity, the complainant can at any time discontinue his suit upon an application to the court, and paying the costs of the defendant, as he likewise may do at law. In criminal prosecutions by indictment, which are in the name of the Crown, though originated by private persons, a *nolle prosequi* may be entered by the attorney-general, but not without his concurrence, although the prosecutor desires it. It is very unusual however for the attorney-general to enter a *nolle prosequi* upon an indictment, except upon the application of the prosecutor. Lord Holt says, "the practice began in the reign of Charles II., and that in all Charles I.'s time there was no precedent of a *nolle prosequi* upon an indictment." (6 *Mod. Rep.*, 262.) There can be no doubt of the power of the attorney-general to put an end to criminal informations filed *ex officio* by him; and in the case of informations in the Court of Queen's Bench, a *nolle prosequi* may be entered by the master of the crown-office upon the application of the prosecutor and with the leave of the court. The effect of a *nolle prosequi* in criminal cases is to discharge the defendant for the time, but it does not operate as an acquittal; so that he may be indicted again, and it is said that even upon the same indictment fresh process may be awarded.

NOMENCLATURE, CHEMICAL. [CHEMICAL NOMENCLATURE.]

NOMINALISTS, a sect of the scholastic philosophers, so named on account of the particular tenet by which they were distinguished, and in opposition to the Realists, another scholastic sect. In order to understand the principal point of difference between these parties, which gave rise to long-continued and acrimonious disputation, it is necessary to advert to the doctrines of the ancient philosophy concerning ideas or universals. According to Plato, who appears to have been indebted for his opinion to the Pythagorean school, universals, or, as he called them, ideas, by which are to be understood such things as we express by general terms, have, apart from the mere conception of them by the understanding, an actual and eternal existence in the Divine Mind; and are the patterns or models according to which the individuals of every species are formed, and by which the constitution of each individual is determined. The separate existence of these essences was denied by Aristotle, who taught that forms—which word as employed by him has the same meaning with the ideas of Plato—were eternally united to matter; that unconnected with it they have no existence, and that they are inherent in their objects. Zeno and the Stoics generally ridiculed the belief in such universal natures altogether; and held that the forms of the Stagyrice and the ideas of his preceptor were nothing if distinguished from the notions of them in the mind

and the words by which they are designated. The doctrine of Aristotle was universally received among the schoolmen until after the commencement of the 11th century. But with the revival of dialectic science, which about this time occurred, it began to be warmly controverted. Those who adopted the Stoical doctrine, and affirmed that words or names only were universal, were termed Nominalists; while those who adopted the Peripatetic opinion, and maintained the proper existence of universals, were termed Realists. The honour of forming the sect of the Nominalists is commonly assigned to Roscelin, canon of Compiègne; but its real founder appears rather to have been John, called the Sophist, and supposed by Du Boulay, the historian of the Parisian Academy, to have been chief physician to king Henry I. of France. Be this however as it may, to Roscelin unquestionably belongs the credit of having first raised the sect into eminence. The Nominalist doctrine was highly obnoxious to most of the divines as well as the philosophers of the period, chiefly perhaps, as Brucker supposes (*'Historia Critica Philosophiæ'*), on account of Roscelin having employed it in illustrating the mysterious constitution of the Divine Nature, and thereby laid himself open to the charge of heresy. Notwithstanding the opposition originating in this source which it encountered, many converts were made; and its advancement was greatly promoted by the genius and learning of the celebrated Abelard, who was one of the disciples of Roscelin. So successful was he in his disputes with William de Champeaux, styled the 'Venerable Doctor,' who flourished about the beginning of the 12th century, and was then the principal supporter of Realism, that the pupils of the latter in large numbers forsook their master, and became the followers of his more eloquent antagonist. Throughout the whole of the 12th century the contest between the rival sects continued to be waged. Both parties, by various modifications of their leading doctrines, gradually became divided to a considerable extent among themselves, and a third sect arose, professing to steer a middle course between them, the adherents of which were distinguished by the name of Conceptualists, on account of their holding universality to be the attribute, not of names only, but of conceptions. This sect however obtained but a small share of notice. At this period the Realists, both in number and respectability, had the advantage of their opponents, and the erudition and subtlety of Albert the Great, Thomas Aquinas, and afterwards of Duns Scotus, gave them such a decided predominance, as to throw the Nominalists completely into the shade. In the 14th century William Occam, an English Franciscan friar, and a pupil of Scotus, becoming the advocate of Nominalism when it was seemingly about to expire, effected a revival, and brought it into greater repute than it had ever before enjoyed. The discussion of the question respecting universals was once more renewed, with the utmost virulence and animosity on both sides. Blows were resorted to when argument was exhausted; and not unfrequently debates were terminated by bloodshed. Throughout Germany the opinion of the Nominalists was soon almost universally received, while Realism, being supposed to be more consistent with the doctrines of the church, and patronised by successive popes, prevailed in Italy and other countries where the influence of the Roman see was most powerfully felt. Although numbering among its defenders fewer persons of philosophical eminence than were to be found among the leaders of the opposite cause, it still maintained its wonted predominance. John, the twenty-third pope of that name, having finished his disputes with the Franciscans, who had zealously opposed him on certain matters affecting the privileges of their order, directed severe persecutions against the Nominalists. In the year 1339 the university of Paris published an edict, denouncing the philosophy of Occam, the effect of which however does not seem to have been very hostile to its wider extension. Louis XI., of France, in 1473, likewise issued an edict against the Nominalists, in which it was ordered that their writings should be seized and secured in the libraries by iron chains, to prevent their being perused. The consequence was, that the leaders of the sect fled to England and Germany. In the following year Louis mitigated his edict, which he had issued at the suggestion of the bishop of Avranches, and permitted the study of the Nominalist writings. Thereafter this sect obtained the ascendancy in the universities of France, as it had formerly obtained it in those of Germany. The Reformation, to which a long train of causes had been effectually conducting, put an end to the controversy so long and so fiercely carried on between the two most memorable parties that have ever arisen among the schoolmen, and the contemporaneous revival of letters eventually gave the death-blow to the scholastic philosophy. Among the most eminent supporters of Nominalism, besides those already referred to, may be mentioned Suisset, Buridan, Marsilius ab Inghen, and Oresmius, in the 14th century, and Matthew of Cracow, Gabriel Biel, Gerson, &c., in the fifteenth.

NOMINATIVE. [CASE.]

NONAGESIMAL. The nonagesimal degree of the ecliptic is that point of the ecliptic which is highest above the horizon. Every point of the ecliptic is therefore the nonagesimal degree in succession.

NONAGON. [POLYGONS, REGULAR.]

NONCONFORMITY is the term employed to designate Protestant dissent from the Church of England. It was in the reign of Edward VI. that the English reformed church first received a definite constitution. During the time of Henry VIII. it remained in a great measure

unsettled, and was subject to continual variation, according to the caprice of the king. As organised by Edward, while Calvinistic in its creed, it was Episcopalian in its government, and retained in its worship many of those forms and observances which had been introduced in the days of Roman Catholic ascendancy. In the first of these particulars it resembled and in the last two it differed from the Genevan church. During the temporary restoration of the Roman Catholic faith under the administration of Philip and Mary, great numbers of the persecuted disciples of the reformed faith sought refuge in France, the Netherlands, Switzerland, and other parts of the Continent. Of those who fled to Germany, some observed the ecclesiastical order ordained by Edward; others, not without warm disputes with their brethren, which had their commencement at Frankfort, adopted the Swiss mode of worship, preferring it as more simple, and more agreeable to Scripture and primitive usage. Those who composed this latter class were called Nonconformists. The distinction has been permanent, and the name has been perpetuated. Queen Elizabeth's accession to the throne, in 1558, opened the way for the return of the exiles to the land of their fathers. It was natural for each of the parties of which they consisted, to advocate at home the systems of worship to which they had been respectively attached while abroad; and the controversy, which had been agitated by them in a foreign country, immediately became a matter of contention with the great body of Protestants in their own. It suited neither the views nor inclinations of the illustrious princess who then held the sceptre to realise the wishes of the Nonconformists, or Puritans, as they began to be called, by giving her sanction to the opinions which they maintained, and assenting to the demands which they made. The plain and unostentatious method of religious service which they recommended did not accord with that love of show and pomp for which she was remarkable; and the policy of the early part of her reign, in which she was supported by the high dignitaries both in the church and state, was to conciliate her Roman Catholic subjects, who, in rank, wealth, and numbers, far exceeded the Nonconformists. The liturgy of Edward VI., having been submitted to a committee of divines, and certain alterations, betraying a leaning to popery rather than to puritanism, having been made, the Act of Uniformity was passed, which, while it empowered the queen and her commissioners to "ordain and publish such further ceremonies and rites" as might be deemed advisable, forbade, under severe penalties, the performance of divine worship except as prescribed in the Book of Common Prayer. This Act was only partially carried into effect from the time of its being passed, in 1558, to 1565. But in 1565 it began to be rigidly enforced, and many of the Nonconformists were deprived of their preferments (for notwithstanding their sentiments, most of them had still remained in connection with the Established Church, being from principle averse to an entire separation); many also were committed to prison. The High Commission Court, tyrannical in its very constitution, became still more severe in the exercise of its functions; and at length, in 1593, the parliament declared that all persons above sixteen years of age who should absent themselves for one month from the parish church should be banished the kingdom; and if they returned without licence, should be sentenced to death as felons. These provisions, though directed principally against the Catholics, affected the Protestant Nonconformists with equal severity; and with reference both to Catholics and Protestants who dissented from the Church of England, were unjust and impolitic. The Nonconformists, during the age of Elizabeth, are not to be regarded as an unimportant faction. Both among the clergy and the laity they were a numerous body; and they would have been powerful in proportion to their numbers, had they only been more closely united among themselves. A motion, made in 1561, at the first convocation of the clergy which was held in England, to do away with the ceremonies and forms to which the Puritans objected, was lost by a majority of only one, even though the queen and the primate Parker were well known to be opposed to such a change. In the Commons the Puritan influence was strong; and if that house be supposed, in any adequate degree, to have represented the people for whom it legislated, their numerical force throughout the country generally must necessarily have been great. Without presumption therefore they might have expected that their remonstrances would be listened to, and their grievances redressed. And certainly it would have been wiser in the government to have endeavoured to secure their support, than to have awakened their discontent and provoked their opposition; more especially when the hostile aspect of foreign nations is considered, and when we remember that the English Roman Catholics, whose numbers and power rendered them particularly formidable, were eagerly watching every symptom favourable to the re-establishment of the ancient faith. Nor would it have been a difficult matter to yield to the claims of the Nonconformists. The moderate among them sought not the overthrow of the ecclesiastical constitution, but contended merely that certain rites and observances, which they regarded as departures from the purity and simplicity of Christian worship, should be dispensed with; and, generally, that matters commonly recognised as things indifferent should not be insisted on as indispensable. Doubtless many were less reasonable in their demands, and injustice and persecution tended much to increase their number. A party, at the head of which was Professor Cartwright, of Cambridge, desired a change, not only in the forms of worship, but in church polity also, and would have substituted

Presbytery in the room of Episcopacy. Another party, namely, the Independents, or Brownists, as they were then termed, going still further, wished the disavowment of the connection between church and state altogether. Still there is every reason to believe that slight concession to the demands of the less violent, and the display of a spirit of forbearance, would have satisfied many, would have allayed the dissatisfaction of all, and would have been the reverse of disagreeable to the country generally. Unfortunately an opposite course of policy in this and subsequent reigns was chosen; which ultimately conducted to the horrors of a civil war, the subversion of the regal authority, and those disastrous events which make the history of the 17th century one of the most melancholy pages of our national annals.

Queen Elizabeth died in 1603, and was succeeded by James VI. of Scotland. From one who like him had been the member of a Presbyterian church, and had on more than one occasion expressed his decided attachment to its principles and worship, the Nonconformists, not without reason, expected more lenient treatment than they had met with in the preceding reign. But their expectations were bitterly disappointed. In compliance with their petitions, a conference was indeed appointed and held at Hampton Court, at which nine bishops and as many dignitaries were present on the one side, and four Puritan ministers, selected by James, on the other. The king himself presided and took part in the debate. But no good results ensued. The Nonconformist representatives were loaded with insults, and dismissed in such a manner as might well give birth to the darkest anticipations regarding the fate of the party to which they belonged. Shortly after, a few slight alterations of the national rubric were made, and a proclamation issued requiring the strictest conformity. In 1604 the book of canons was passed by a convocation, at which Bishop Bancroft presided. It denounced severe temporal and spiritual penalties against the Puritan divines, and was followed up by unsparing persecutions. In spite however of all the means employed for its eradication, the cause of Nonconformity advanced. In the church itself there were many of the clergy who held the Puritan opinions, though they deemed it inexpedient to make a very open display of them, and who sighed for a change; and the number of such was largely augmented by the alteration which James made in his creed, from Calvinism to the doctrines of Arminius.

The son and successor of James, Charles I., adopted towards the Nonconformists the policy of his predecessors. His haughty temper and despotic disposition speedily involved him in difficulties with his parliament and people. In carrying into execution his designs against Puritanism, he found an able and zealous assistant in Archbishop Laud, under whose arbitrary administration the proceedings of the Star Chamber and High Commission Court were characterised by great severity. Many Puritans sought for safety and quiet in emigration; and the colony of Massachusetts Bay was founded by them in the New World. But a proclamation by the king put a stop to this self-banishment; and thus even the miserable consolation of expatriation was denied. Hundreds of Puritan clergymen were ejected from their cures, on account of their opposition to the Book of Sports, published in the previous reign. Calvinism was denounced by royal authority, and severe restrictions laid on the modes and times of preaching. But a change was approaching. In 1644 Laud was declared guilty of high treason and beheaded; and about five years after, Charles shared the same fate. The parliament abolished Episcopacy and everything in the Church that was opposed to the model of the Genevan church.

During the Protectorate, Presbytery continued to be the established religion. Independency however prevailed in the army, and was in high favour with Cromwell. Under his government the sects of the Quakers and Baptists flourished; and other sects, some of which held the wildest and most visionary tenets, sprung into existence. All were tolerated. Episcopacy only was proscribed; and the Nonconformists, in their hour of prosperity, forgetful of the lessons which adversity should have taught them, directed against its adherents severities similar to those of which they themselves had been the objects. The Restoration in 1660 placed Charles II. on the throne of his ancestors, and led to the restitution of the old system of church government and worship. The Act of Uniformity was passed in 1662, by which all who refused to observe the rites as well as subscribe to the doctrines of the Church of England were excluded from its communion, and in consequence exposed to many disadvantages and to cruel sufferings. During the same reign were passed the Conventicle Act, which subjected all who presumed to worship God otherwise than the law enjoined to fine and imprisonment, and punished the third offence with banishment; the Five-Mile Act, which banished to that distance from every corporate town the Nonconformist clergy, and forbade them to officiate as schoolmasters except on condition of their taking the oath of passive obedience; and the Test Act, which, though directed against the Roman Catholics, pressed with equal severity against Protestant dissenters, and excluded from offices of trust in the state those who refused to receive the eucharist according to the rubric of the Church of England. After this time dissent continued in a very depressed state, and had to struggle with various fortunes, until the reign of William III., when the Toleration Act gave immunity to all Protestant Dissenters, except Socinians, from the penal laws to which they had been subjected by the Stuart dynasty. The benefits conferred by this measure were indeed subsequently much abridged by the Occasional

Communion Bill, which excluded from civil offices those Nonconformists who, by communion at the altars of the Church, were by the provisions of the Test Act qualified to hold them; and by the Schism Bill, which restricted the work of education to certificated churchmen. After the accession of George I., however, these laws were repealed, and since then, by the removal of the Test Act, and by the passing of the Acts relating to registration and marriage, dissenters have been allowed the peaceable enjoyment of the rights of conscience, and all the political privileges of their fellow-citizens. It would be a task of some difficulty to enumerate the various sects which may be classed under the general head of Nonconformists. The chief denominations are the Presbyterians, Independents, Baptists, Wesleyan, and Calvinistic Methodists, and Quakers. [BAPTISTS; METHODISM; DISSENTERS; QUAKERS, &c.]

NONES. [KALENDAR.]

NONJURORS. [THEOLOGY.]

NONSUIT. If a plaintiff, having commenced a civil action, is guilty of any neglect or default in prosecuting such action according to the practice of the court in which it is brought, he is adjudged *not to follow* or pursue his remedy, and a judgment of *non prosequitur*, or *nonsuit*, is entered, upon which he becomes liable to pay costs to the defendant, and in ancient times a fine to the king for making a false complaint. This is the general meaning of the term; but according to modern practice it has a more limited signification, the phrase *non pros* (*non prosequitur*) being now used to describe the consequence of most of those defaults on the part of the plaintiff which were formerly comprised under the general term nonsuit. Anciently, when it was the practice for the jury to stand at the bar of the court to hear the evidence on a trial, they withdrew, after the judge had summed up the proofs, to deliberate upon their verdict. On coming back to the bar to deliver their verdict, and before they delivered it, the plaintiff was called in order to be ready to answer the fine which became due to the king for his false complaint, in case the decision was against him; and if, upon this call, he did not appear, no verdict could be given upon the evidence either for the plaintiff or the defendant, and the former was said to be nonsuited. Hence arose a practice that when the plaintiff perceived that the evidence given was insufficient to support his action, and that the verdict would probably be against him, he voluntarily withdrew himself, and did not appear when called; the consequence of which was a nonsuit, which was less disadvantageous to him than a verdict for the defendant, as it did not preclude him from bringing a new action. This practice led to a further innovation upon the ancient proceeding, and it has long been the usual course for the judge to order the plaintiff to be called, or, in other words, to direct a nonsuit, if, upon the whole of the case in support of the action, he is of opinion that there is no evidence upon which the jury would be justified in finding a verdict for the plaintiff. In consonance to the ancient practice, however, by which the plaintiff might in all cases appear when called to answer for his fine, and so prevent a nonsuit, he cannot, except in the County Court, be *compelled* to be nonsuited; and therefore he may insist upon the evidence being left to the jury. It is to this practice of calling the plaintiff, when his evidence, as delivered in court, is insufficient to support his action, that the term nonsuit is now restricted. The consequences of a nonsuit are, that the jury are discharged from finding a verdict, and the plaintiff pays the costs of the suit; but he is still at liberty to commence a new action against the defendant upon the same matter, if he should afterwards be provided with more complete evidence. In the County Court the judge is expressly authorised by statute, if not satisfied with the plaintiff's case, to enter a nonsuit.

NONYLENE ($C_{18}H_{18}$), *Elaene*. A hydrocarbon belonging to the family of biatomic radicals, produced by the destructive distillation of hydroleic and metoleic acids. It is a colourless liquid of a penetrating odour, insoluble in water, but soluble in alcohol and ether. It boils at about 230° Fahr., and is lighter than water. Concentrated sulphuric acid is said to have no action upon it.

NORDHAUSEN SULPHURIC ACID. [SULPHUR: *Sulphuric Acid*.]

NORIUM (No), a metal said to be contained in the Zircons of Norway and Sweden. Its existence cannot be said to be clearly established.

NORMA, the Rule, a constellation of Lacaille, situated between Scorpio and Lupus. It contains no stars of conspicuous magnitude.

NORMAL. This word (from *norma*) is generally used to mean a perpendicular drawn to the tangent line of a curve or the tangent plane of a surface. It formerly meant simply *perpendicular*. [TANGENT.]

NORMAN ARCHITECTURE. In the article GOTHIC ARCHITECTURE, that form of Round-arched Gothic known as Norman or Anglo-Norman is spoken of as one of the local modifications of that generic style which, springing from the debased Roman architecture, has received the name of Romanesque. Under the heading ROMANESQUE ARCHITECTURE, the general characteristics of the style will be described. Here we shall speak only of the variety which prevailed in this country from the middle of the 11th till near the close of the 12th century, or from the date of the Conquest to the close of the reign of Henry II., 1189. It was preceded by the Anglo-Saxon, a style which differs from it in no essential particular, being in fact little more than a rude imitation of

the architecture practised on that part of the Continent with which the Anglo-Saxon princes and priests were in most intimate communication: and the more important buildings at least were probably executed under the direction or with the assistance of Norman architects. But as this style has received a specific name, and is usually treated as a distinct style, it will be more convenient to defer our notice of it to a separate heading. [SAXON ARCHITECTURE.] At the same time, as we said of the various styles of Pointed Gothic, it is important to bear in mind that none of the styles of English architecture are separated by sharply defined dividing lines. As each style of Pointed Gothic grew out of a preceding style, and became gradually absorbed in its successor, so did the Round-arched Anglo-Norman gradually emerge from the rude Anglo-Saxon, and, after a vigorous independent existence of a century's duration, quietly and by degrees make way for or become developed into the Early English, or First Pointed Gothic.

In considering Anglo-Norman architecture, it should be remembered that there are few buildings remaining which are in this style throughout, though there are many which retain detached parts and features belonging to and some which mainly consist of it, more or less intermixed however with what is of later date and different in style. A great deal of Norman work is to be met with in the older parts of several of our cathedrals, and also in many smaller churches, such as Barfreston in Kent; New Shoreham, Sussex; Iffley, Oxfordshire; Steetly, Derbyshire, &c., which, having remained comparatively untouched, exhibit, although upon a limited scale, more of the Norman style and the peculiar mode of applying it than many larger edifices, notwithstanding that these latter occasionally present decorative features in this style which do not occur in buildings of a less pretending character. The older parts of Canterbury, Durham, Winchester, Gloucester, Peterborough, Ely, Norwich, Lincoln, and Oxford cathedrals are in this style. The nave and choir of Norwich in particular (founded in 1096), with the exception of pointed windows of later English character inserted in the upper part of the choir, are almost entirely Norman, of which they present a very fine example. Very little, however, remains to show the style of exterior composition employed by our Anglo-Norman architects in their larger edifices. The west fronts of Rochester and Lincoln cathedrals are almost the only parts that can be considered as specimens of Anglo-Norman architecture; yet each of them has many interpolations of other styles. The lower part of the former is entirely Norman, and has a remarkably fine though not very spacious centre doorway; but the large window over that entrance, in the Third Pointed or Perpendicular style, is so very prominent a feature, as greatly to take away from the effect that would else be produced by the other parts. The front of Lincoln presents little more than a surface decorated by tiers of small columns and arches of the kind known as arcades [ARCADES], which form so characteristic a feature of Norman architecture. These arcades are frequently

Arcades from the front of Lincoln Cathedral.

carried in several tiers over each other to a considerable height, as in the tower at St. Edmunds, Bury, and the S.W. wing of Ely cathedral. Considerable variety is given to them by occasionally doubling the columns and varying the capitals, and still more by causing the arches to intersect, thereby bringing into strong relief the form of the pointed arch; though it is quite certain that this intersection did not, as some writers have suggested, give rise to the pointed arch, since it was in existence long before. [ARCH.] Wherever a superior degree of decoration was aimed at, the Anglo-Norman builders seem to have contented themselves with covering what would else have been blank surfaces with these tiers of columns and arches. The two transept towers of Exeter Cathedral, the front of Castle-Acre Priory, and of St. Botolph's Priory, Colchester, present little more; consequently, notwithstanding the variety as to detail, there is a very great sameness as to general composition and design.

In the interior of buildings this style exhibits itself more decidedly, owing not only to the perspective effect of a succession of spacious open arches, as in the Naves of Norwich, Durham, Rochester, Chichester,

Ely, and Peterborough cathedrals, but also to greater size and massiveness. Although such difference of character may at first appear some-

Tower of Bury St. Edmunds.

what incongruous, it being usual to find more minute and delicate forms employed for the internal parts of a building, the reason for it is evident; the tiers of pillars and arches on the exterior of Norman structures are merely decorations of the surface, while the arches and piers within are essential parts of the fabric. Instead of anything like lightness, we here meet with extraordinary massiveness arising from the immense bulk of the piers from which arches spring: which character exhibits itself most strikingly when, as is the case with some of those in the nave of Norwich cathedral, the piers are merely short cylinders, with a kind of plain capital, and are not formed by shafts attached to a central mass of masonry. In the building just mentioned some piers of that description are ornamented on their surface by spiral grooves or flutings; and we may here remark that in that and other examples both cylindrical and clustered piers occur, not only in the same building, but in the very same part of it; and that great variety of detail and ornament is frequently observed in the mouldings of arches, columns or piers and their capitals, though they are uniform as to size, and compose a single range. Owing to the great diameter required for the supports of larger arches below, the mere pillar-shape was never employed for them, for although pillars of slender proportions were introduced for such purpose, it was only as *pier shafts*, or when the entire pier was made to consist apparently of a cluster of slender pillars, as some of those in the nave at Durham. Slender detached pillars are indeed of not infrequent occurrence, but it is only to support small arches, as where a window is divided into or composed of two or more such arches, or in the triforia and other galleries within the building, where openings corresponding with the larger arches below are divided after the same fashion, and therefore do not form a continued arcade, but coupled or tripled arches at intervals, between the main piers. Sometimes the larger arches below, instead of being connected and resting upon the general capital of the pier, spring from *nook-shafts* or slender attached pillars, within the re-entering angles of the pier itself, the face of which was either left as a plain space dividing those pillars and the arches from the adjoining ones, or else decorated with another shaft carried quite up to the springing of the vaults, and therefore very appropriately distinguished by Whewell by the term *vaulting-shafts*. The nave of Chichester, and the Abbaye aux Hommes at Caen, give a combination of both these modes. But although attached pillars and shafts were almost uniformly of exceedingly tall and slender proportions, we occasionally meet with pillars short and stumpy and with bulky capitals, although the arches are very narrow, and the pillars themselves in situations where more delicate forms would have been sufficient. Of single columns approaching to the proportions of ancient Roman columns, like those which are found in the Romanesque buildings of Italy, Anglo-Norman structures afford no true examples. The only instances are in Semi-

Norman or Transition buildings, like that part of Canterbury cathedral called Becket's Crown, (see the cut, col. 973), where columns partaking very much of the Corinthian character, though somewhat bolder and

more masculine, are employed as piers to support the arches (not round-head, but pointed); or they are rather coupled columns united back to back. Within crypts very short detached single columns were employed

Interior of Durham Cathedral.

to support the arches of the vaulting, but this deviation from the usual practice would seem to have been occasioned merely by the local peculiarities of such subterraneous apartments, and consequently it can hardly be considered as characteristic of the style itself.

The plan and general arrangement of a Norman church are the same as have been followed in subsequent styles. [CHURCH.] The larger Norman churches are cruciform with a low massive tower rising from the intersection of the arms of the cross. Smaller churches consist only of a nave and chancel. Choirs and chancels were frequently apsidal, as were also the chapels attached to the larger churches, but many of these apses have been removed. [APSE.] Norwich cathedral affords a good example of the Anglo-Norman apse. Sometimes in these apses the high altar was attached to a reredos, which was fixed between the piers, and a space left behind for the passage of processions which could thus on solemn occasions make the entire circuit of the church. Numerous examples however occur in which the chancels are rectangular in plan. The aisles were often extremely narrow, and some small churches occur without aisles. Choirs were usually vaulted, but no example we believe occurs of a vaulted nave. *Crypts*, some of them of fine proportions, considerably enriched, and excellent specimens of masonry, are common under cathedrals and

its principal component parts and separate features; but though not numerous in themselves, it would occupy some space and require a great number of explanatory cuts, to attempt to notice them with much particularity, for few as are the general forms, and unvaried as is the general character, the diversity of detail and minutiae is exceedingly great.

Doorways, even in small and otherwise plain Norman buildings, and even when small in themselves, seem almost always to have had a great deal of embellishment bestowed upon them; and many have therefore been preserved in buildings, in every other part of which nearly all traces of the original edifices have been obliterated by subsequent alterations: instances occur, however, where the doorways have merely a plain dripstone moulding above the arch. In many instances doorways are very deeply recessed, and in proportion to the aperture or door itself the dressings or decorations occupy a great space: this not only allowed great latitude in other respects, but enabled the architect to make what would else have been an insignificant feature, an important one in the design. In some cases, as at Malmesbury Abbey church, there are no fewer than eight concentric arches recessed one within the other. The tympanum, or stone which in many examples fills the semicircular head of the arch, is usually covered with sculpture. We give a cut of the doorway of Barfreston church, Kent, which, although small, will illustrate the richness and elegance of character of a Norman doorway, and serve as an example of a square-headed door, where the arched space above it is filled up with sculptures. The figure in the centre of the tympanum, it will be observed, is that of the Saviour, who is seated within an aureole [NIMBUS], his right hand raised, and his left resting on a book. This is a very usual decoration on Norman doorways, and is in allusion to the passage "I am the door," &c.; but other scriptural, legendary, or symbolical figures are also frequently represented. Symbolical sculpture is indeed very largely introduced in every part of a Norman church of the better class.

Windows had seldom much decoration; they were generally small and placed at a considerable distance from each other; sometimes they were merely plain apertures in the wall, and rarely more than scantily ornamented. We give two specimens of Norman windows, one consisting of a single opening, but more than usually enriched, the other divided by a central pillar. Triple windows, and window-like openings in internal galleries, divided by two pillars into three arches, of which the middle one is wider and loftier than the others, also occur. There are also windows in this style which, though narrow, are of very considerable dimensions as to height, like those at the east end of Canterbury Cathedral. In regard to this feature, the Norman and Pointed Gothic styles differ essentially, as much, if not more, than they do in the mere form of their respective arches: for besides that windows are very secondary features in the one style, whereas they are among the principal and most characteristic features in the other, Norman windows have neither mullions nor transoms, nor any tracery or open compartments in the head of the arch; for even where the aperture is divided into two smaller arches, resting upon a central pillar, the space or head between those arches and the larger one which includes them is never perforated or otherwise decorated. Hence the windows themselves were necessarily limited as to size: not but that it would have been very possible to increase the number of openings by means of additional pillars, and by afterwards perforating the general head of the window above the smaller arched divisions, although not with equal consistency as in Pointed Gothic, where the mouldings of the mullions are continued upwards and form the ribs of the tracery, however complicate it may be. Sufficient hints for such

Doorway, Barfreston.

large churches: the crypt of Canterbury Cathedral is one of the finest. [CRYPT.]

Having spoken of the style generally, we shall now briefly describe

purpose might have been found in some of the intersecting patterns of ornament which occur among the exterior enrichments of Norman

Window, Caston Church,
Northamptonshire.

buildings. As a very peculiar and interesting specimen of Anglo-Norman architecture, and for the purpose of showing how, by increasing the number of openings and pillars, windows might have been extended in this style, we here exhibit a sketch of an external staircase leading to the registry at Canterbury.

In this example there is somewhat to remind us of the open galleries of the Italian Lombardic, especially of those upon sloping lines beneath pediments, with this difference, that here the arches form a horizontal line. We have here also an instance of what was by no means uncommon in small arches in this style when they are not pierced through, which is, that the inner margin of the arches is formed by a chevron moulding which scallops them.

Pier-Arches, that is, open arches resting upon piers, as those within churches, do not materially differ in design from those which ornament doorways, except that they are not so profusely decorated, and the archivolt mouldings do not occupy by any means so much space in proportion to the width of the opening. The arches themselves being uniformly circular (though in some few cases either somewhat more than a semicircle or prolonged perpendicularly to the impost), exhibit so far no variety; still as regards the entire aperture, of which the arch itself forms the head, there is very great variety of character, according to the proportion which the heights of the supporting piers bear to the diameter of the arch, or opening between them. About twice the breadth appears to have been the average height of arches (namely, openings) between piers; when much above that standard they may be called lofty (as the arches of the nave at Durham); and when much

Durham cathedral are so ornamented: zigzag or chevron lines were also employed for decorating the surfaces of piers and columns, and

beneath it, they may be considered of low proportions. Besides the difference of character thus occasioned, much is also produced both by the form and proportions of the piers themselves. A circular or octagonal pier, for instance, appears much more massive than one composed of clustered shafts, &c., though the general diameter of the latter may be the same, or even somewhat more. Though we cannot pursue this point any further, we would recommend those who feel at all interested in the subject to make such comparisons for themselves; and they will doubtless find that they will be led on to make many others, and to enter into original investigations.

Vaulting is an important and characteristic feature in Norman architecture. In early buildings plain semi-cylindrical, or as it is termed barrel or waggon vaulting occurs, as in the White Chapel of the Tower of London. More common is the quadripartite or Roman vaulting, as in the Crypt of Canterbury Cathedral. Groined vaulting is usual in later examples. The crypt at Westminster Abbey, and the cathedrals of Winchester, Worcester, and Gloucester, afford characteristic specimens of Norman vaulting. Vaulted ceilings occur in Norwich, Durham, Peterborough, and the choir of Canterbury cathedrals. Over the vaulting of the aisles was in the large churches a Triforium. [TRIFORIUM.]

Buttresses, to which buildings in Pointed Gothic are indebted for so much of their character and effect, can hardly be said to exist in Norman architecture. The enormous thickness of the walls and their solidity, owing to the smallness and infrequency of apertures in them, rendered such additional support unnecessary, even when the vaulting of the roof was large and bold. Hence nothing more than either *buttress*, or *pilaster strips* (as they are conveniently termed by Mr. Whewell), were introduced, and these more for the sake of producing some variety and degree of expression than for actual strength, their projection beyond the general plane of the wall being very inconsiderable, and no more in fact than that of the corbelled parapet, or *corbel-table*; consequently buttress-strips do not so properly constitute projecting surfaces, as the intermediate spaces of wall form recessed compartments, or large pannels. The parapet itself was seldom more than a plain corbel-table, without battlement; but sometimes, instead of forming a horizontal line, the lower edge of the corbel was what might be described as *embattled-reversed*, that is, indented like a range of battlements hanging downward, or else made *wavy*, or scalloped with curves.

But the more common mode was to make the lower edge of the corbel table straight, with a series of corbel mouldings beneath it frequently intersected by small blocks at intervals (after the manner of modillions), which were either left plain or sculptured with grotesque heads and figures. Occasionally again the corbelling assumed the form of a series of small interlacing arches.

Pillars and Columns, with which the massive circular arch-piers, or piers with nook-shafts, are not to be confounded, exhibit great diversity of character, both as to proportions and decoration, from the rudest and plainest forms to either the lightest or the most enriched. Neither are the two terms precisely synonymous, it being as well to observe the distinction made between them by Whewell, and to restrict the latter term to such pillars as approach to the general proportions and character of classic columns. *Pillars*, on the contrary, have very great variety of proportions, either much below or greatly above such standard, being generally adapted to the load they have to sustain, without any regard to classic or any other metrical proportional. The shafts are for the most part plain, though instances occur of their being carved (as was oftener than not the case with the columns of Lombardic porches); and in the undercroft at Canterbury Cathedral there are pillars whose shafts are fluted spirally. Raised mouldings, intersecting each other spirally so as to form a diamond-pattern on the surface, are by no means unfrequent; and some of the circular arch-piers in

were disposed either annularly, in horizontal rings, or spirally. Of these and some other varieties specimens are here shown.

With respect to *Capitals*, the diversity is so great as to render it impossible, at least here, to attempt to classify them, or particularise even the leading varieties. While some are both rude and plain, others are remarkable for the delicacy of workmanship and the taste shown in their enrichments: some, though they do not lack ornament, are either too poor and insignificant, while others again, though quite

plain, have something pleasing in their mass and contour, and in the proportion they bear to the height of the shafts. Of the plainer sort

Oxford Cathedral.

Mouldings are of great variety, in some instances very elaborately carved, and always ornamental features in Norman buildings. One of the most favourite and characteristic is the chevron, or zigzag moulding, which is used alike for archivolts and other decorative features. Hardly less characteristic is the billet, or alternate billet moulding, which occurs in all classes of churches. Other kinds of frequent occurrence are classed as the pellet, the lozenge, the indented, nail-head, cable, beak-head, medallion, star, &c.; but there are a great variety of others, and among them the more complex descriptions, which fall under none of those classes. The following are a few of the almost numberless varieties which exist: others will be recognised in the cuts of windows, doorways, &c.

As already indicated the *Towers* in this style were usually low, and massive; square in plan, with small narrow windows, and in the early examples plain, or but little ornamented. In the more important and

of capitals, the most common shape of those occurring in Anglo-Norman buildings is what Mr. Whewell designates the *Cushion Capital*, and which is formed by an inverted cone, of convex contour, spreading up towards the abacus, but intersected by four planes, producing as many flat surfaces or sides answering to those of the abacus. This will be rendered more intelligible by the annexed examples from Rochester cathedral, although they instance varieties of the cushion capital, the stem or circular part of each being cleft, whereby the planes or faces forming the sides become scalloped: the cushion capital will also be recognised in some of the succeeding examples.

Of the variety of sculptured and enriched capitals, the specimens here annexed do not go far towards conveying an adequate idea, nor are they the very best that are to be met with; nevertheless they may suffice. The first two, which we have selected for the sake of comparison, are foreign, namely, from Jumieges and Sanson sur Rille; the next are from St. Peter's, Northampton (a church which affords a wonderful variety of enriched Norman capitals), and Steetly church, Derbyshire: the last of these is as remarkable for the Grecian character of the intertwining volutes carved upon it, as the first is for its striking general resemblance to the Corinthian capital. The final examples, from Oxford cathedral, are very chaste in design.

later buildings they were, however, often adorned with a profusion of arcades, and sometimes enriched with carving. Occasionally octagonal

or polygonal towers are seen, as at Ely cathedral. Round towers are not unusual in the churches of the eastern counties, especially Norfolk and Suffolk. Norman towers were originally capped with a steep pyramidal roof of stone, or tiled; a form which was elongated into the stunted pyramidal spire, and afterwards probably led to the ordinary spire, in like manner as its ornaments of animals' heads and figures may have suggested the first idea of crockets. Examples of this kind of roof are not often met with in this country, they having usually been replaced by a spire of later date, or removed to make way for an embattled parapet. We therefore subjoin (col. 973) a sketch of one of contemporary date, on the tower of Than church in Normandy.

The course of Norman architecture was unquestionably on the whole towards richness and refinement. Yet it was always distinguished by mass and majesty. In the earlier examples, rude and stern, it gradually put off something of its austerity, but always retained a certain severe nobility of aspect. As it passed into the First Pointed style it dropped one after another of its earlier characteristics, and assumed a lighter and more elegant appearance; but it is noteworthy that as pointed arches began to mingle with semicircular, the ornamental details of the building became less florid and fewer, but chaster and more correct in design, and more finished in execution. This Transition or Semi-Norman style is briefly noticed under *GOTHIC ARCHITECTURE*: but in a general sketch, like the present, it is

unnecessary to dwell on a style that is essentially without individuality; its character being a compound of the styles between which it

stands. A good example of this style is that portion of Canterbury Cathedral called Becket's Crown, erected in 1184.

Becket's Crown, Canterbury.

As the best way perhaps of impressing on the memory the leading characteristics of Norman architecture, we shall conclude by briefly contrasting them with those of the Pointed Gothic style.

NORMAN.	POINTED GOTHIC.
Round-headed arch.	Pointed arch, varying in proportion.
No tracery in windows.	Windows with mullions, transoms, and tracery.
Buttress-strips.	Buttresses rising in offsets or stages.
No pinnacles, properly so called.	Pinnacles.
No battlements, except in castles.	Battlements in the ecclesiastical as well as military style.
Spires scarcely known.	Spires characteristic features.
Splayed surfaces of rare occurrence.	Splays for receding parts, universal.
Niches infrequent.	Niches very general.
Windows generally small and few.	Windows spacious and numerous.
Horizontal lines and arrangements prevalent.	Vertical lines and arrangements.
Arch-piers very massive.	Arch-piers comparatively slender.
Vaulting simple and mostly plain.	Vaulting more complex and decorated.

NORMANDY, CUSTOMARY LAW OF. Previous to the first Revolution the several provinces into which France was divided were chiefly governed by a system of laws which, arising originally from local usages, became in after time embodied in a code which obtained the sanction of the sovereign, and became the established law of the province. These codes were styled customs, *coutumes*, and have been largely and learnedly commented upon by various jurists of the period, whose commentaries were often received as law. The customary of Normandy ranks among the most ancient of these customaries. According to it, laws, customs, and usages, were regulations of a very different authority: the laws were enacted by the sovereign, reduced to writing, and registered by the exchequer, afterwards denominated the parliament of Rouen; customs originated with the people, and in time were compiled and reduced to writing by the supreme authority. Hence the difference between *loi*, *us*, and *coutume*, as understood in the ancient provinces of France. By *loi* was understood the royal ordinances and Roman law; by *coutumes*, or customs, those regulations which had been compiled and received the sanction of the sovereign; by *us* or usage, such regulations as had not been reduced to writing. Normandy, both as an independent state, and after its annexation to the crown of France, may be said to have had three distinct codes; *le grand coutumier*, or ancient customary; *la charte aux Normands*, or Norman charter; and the modern custom. The ancient and modern custom related more particularly to property, &c; *la charte aux Normands* to the political liberty of the subject. The Norman charter was granted by Louis X., its principal object being to restrain the kings of France from imposing too heavy burdens on their Norman subjects. This charter was confirmed six times from its promulgation to the reformation of the customary by Henry III., which affords a fair presumption that it had been often violated. The customs of Normandy were first reduced into writing by a private hand in the reign of Louis IX., about the year 1229, which corresponds with 14 Henry III. of England. Being subjected to examination under Charles IX., many of its reforms were sanctioned by the high authority of the Chancellor l'Hôpital, and the modern reform dates from 1585, under Henry III. This custom was known throughout France by the appellation of *la sage coutume*. The number of provincial customs of France before the Revolution were reckoned at eighty, and its local usages at nearly three hundred. In Normandy there were no less than twenty-two different modes of devising patrimonial estates, corresponding to the number of vicomtés or districts of which the province was composed.

L'Ancien Coutumier is divided into 125 chapters, nearly two-thirds of which are devoted to regulate the duties of the judicial officers, the proceedings in the different courts, and the respective rights and obligations of the kings of France, the dukes of Normandy, the feudal lords and people. The transmission of property by wills and inheritance, which occupies so large a portion of modern law and of the reformed Norman law in the 16th century forms a very small portion of the *Ancien Coutumier*.

The modern or reformed *Coutumier de Normandie* is divided into 24 chapters, which are subdivided into 622 articles. The modern *Coutume* was reformed at Rouen on 1st July, 1585, by commissioners appointed by Henry III. of France with the concurrence of the provincial authorities known as *les gens des trois états*, or three orders representing the nobility, clergy, and people.

Among the peculiar customs of Normandy was *la clameur de Haro*, which custom still prevails in the Channel Islands, where the Norman ancient customary is the principal law; and may be denominated a call upon the supreme authority for justice, "*appellatio ad principem ad opem in lite ferendam*." The term is considered to be derived from Duke Rollo, or as the name is variously spelt, Raoul, Roul, and Rou (Du Moulin's '*Hist. de Normandie*,' lib. i. c. 9, and lib. vii. c. 20), "*Haro*" being a corruption of the cry Hal, or Ha Rou, by which this prince, who was remarkable for his justice, is said to have been invoked. It is thus practised in the Channel Islands. When an individual considers that another is infringing upon his right of property, he, in the presence of two witnesses, protests against the proceedings, and, crying out three times "*Haro*," summons the trespasser to desist. He then applies to the judicial authorities, declaring what he has done, and proceeds to the register, or record office, where note is taken of the particular circumstances of the case; he afterwards brings an action against the trespasser. If he neglect to do so, then the person against whom the "*Haro*" was cried may bring his action against him who cried it, and oblige him, if he cannot justify his proceedings, to desist and submit to the judgment of the court. Upon the action of either of the parties the decision is generally referred to what is termed *une vue de justice*, or an examination by the court of all the circumstances on the spot itself. The party condemned is subjected to a small fine and pays all costs; in addition to which he was formerly punished by what was termed *un regard de château*, that is, twenty-four hours' imprisonment; the imploring the aid of the prince without cause and the invasion of another's possession being accounted equally criminal. In ancient Normandy parties resorted to the *clameur de Haro*, in cases of assault and battery, but that part of the custom has never prevailed in the Channel Islands.

The president or chief judicial officer in Guernsey is still styled baillif, the name by which he is designated in the ancient *Coutumier de Normandie*. In Jersey he is styled bailly, by which name he is

designated in the modern customary of the same island. In Alderney this officer is styled juge. In each island he is appointed by the crown; and his authority continues much the same as laid down in the ancient *Coutumier*. It is his duty to maintain order, to decide according to law and usage all disputes arising between parties residing within his jurisdiction; and to put down all thieves, incendiaries, and other malefactors.

The first commentary on the Grand Coutumier of Normandy was written by Rouillé, a jurist of Alençon (Guillaume de Rouillé, 'Commentaire sur la Coutume de Normandie,' fol. 1534, reprinted in 1539). It was followed by that of Terrien of Dieppe, which was published in 1574, after his death (Guillaume Terrien, 'Commentaire sur les Coutumes anciennes de Normandie,' fol.). After the revision of the customary in 1585, several modern commentaries appeared. The best editions are 'Décisions sur chaque article de la Coutume de Normandie,' &c., par Pierre de Merville, Paris, 1731, fol.; Bérault, Josias, born 1563, died 1640, 'Commentaire sur la Coutume de Normandie,' Rouen, 1684, in fol.; Basnage, Henri, born 1615, died 1695, 'Commentaire sur la Coutume de Normandie,' Rouen, 1678-1681; Godefroy, Jacques, 'Coutume du Pays et Duché de Normandie avec les Commentaires de Bérault, Godefroy et d'Aviron,' Rouen, 1684, 2 vols. fol.; Flaust, Jean Baptiste, born 1711, died 1783, 'Explication de la Jurisprudence et de la Coutume de Normandie,' 2 vols. fol.; Pesnelle, 'Coutume de Normandie avec la observations de Roupnel,' Rouen, 1759, in 4to; Houard, David, born 1725, died 1803, 'Traité sur les Coutumes Anglo-Normandes,' Rouen, 1776, 4 vols. 4to.

Hale, in his 'History of the Common Law of England' (chap. vi.), maintains that the 'Coutumier of Normandy' was written long after Glanville's tract, which was written in Henry the Second's time; and that the Norman collection was made after the time of Henry II. appears from its mentioning his coronation, and appointing it for the limitation of actions ancestral, which must at least have been thirty years after. "Nay, the 'Coutumier' appears to have been made after the act of settlement of Normandy in the crown of France, for therein is specified the institution of Philip, king of France, for appointing the coronation of king Richard I. for the limitation of actions, which was after the said Philip's full possession of Normandy." Hale's opinion is, that "this similitude of the laws of England and Normandy was not by conformation of the laws of England to those of Normandy, but by conformation of the laws of Normandy to England."

NORROY. [HERALDRY.]

NORTH AMERICAN INDIANS. The name of Indians was applied to the indigenous inhabitants of America on the first discovery of that continent, on the supposition that it formed a part of Asia, and the name has been retained ever since. By the great majority of those of South America considerable progress in civilisation had been made at the time of the discovery, as is proved by our knowledge of the kingdoms of Peru, Quito, and, farther north, Mexico, and vestiges of this civilisation have been even preserved. A further portion was reduced to a state of semi-civilisation by the exertions of the Roman Catholic missionaries, and their influence is still visible in Paraguay and other places. Still there are a few tribes, as the Abipones in Paraguay [ABIPONIANS, in GEOG. DIV.], the Guarinis in Brazil, and a few others, which maintain a species of independence by living apart from the more civilised portion. But in North America, though pressed on all sides by the rapid increase of the immigrant European population, dispossessed of the most fertile parts of their territories, and vastly reduced in numbers by successive wars and the introduction of European diseases and vices, they have, with few exceptions, refused to amalgamate, or accept the opportunities of improving their position, but maintain their savage tastes, manners, and customs, with a precarious independence, depending on their withdrawal to still wilder regions as civilised man advances on their position. Their numbers now are not estimated at more than 1,500,000 in the whole; they are scattered over a vast region, and they consist of a great variety of nations, as they term themselves, from the fact of their speaking a variety of languages, said to be full 500 in number, though certainly many roots are common to most of them.

George Catlin, in his 'Letters and Notes on the Manners, Customs, and Condition of the North American Indians,' London, 1841, says that there is no idolatry found amongst them; all worship or acknowledge one Great Spirit, and know nothing of any intermediary. The Mandans he thinks the relics of the mythic Welsh expedition of Madoc. They have little government, though each tribe has a chief. The chief, however, has little real authority, and is in fact only a leader in war. They have no established laws beyond the few penalties established by custom, and their punishments when inflicted are cruel. War is decided on by the chiefs in council; the chief's pipe, coloured red, is sent through the country by messengers, and every volunteer draws the smoke once through its stem, and thus pledges himself to serve: but he is still a volunteer, and is only restrained by pride, or the shame of retreat, or by feeling an immediate interest in the contest, from quitting the chief whenever he chooses. He adds that little progress has been made in mechanical arts, and the figures cut on rocks or in turf show but little skill in design.

The physical character and appearance of these natives has been given in the Man of AMERICA, in the GEOG. DIV., col. 294; but we may add that on the whole they do not exceed the average stature of Europeans, but in some tribes the men exceed six feet in height; that

they are more formed for fleetness than for strength; that they have the virtues and vices of most savage tribes, hospitality and protection to strangers who trust them, revenge against enemies, want of prudence, and intemperance. Names are given to about 120 tribes or nations, most of them speaking a language different from the rest, though some of them now number but a few scores, and many but a few hundreds. We shall only notice a few of the more important of these tribes, taking them alphabetically, in accordance with our general arrangement.

Algonquins. [ALGONQUINS, in GEOG. DIV.]

Arapahas, a small tribe of about 4000 souls, inhabiting the plains of the river Platte, at enmity with the Crows.

Araphoes are neighbours of the Camanches, inhabiting the Rocky mountains, with Santa Fé on the south and the coast of California on the west. They, with the Navahoes, who inhabit nearly the same districts, have much harassed the American settlers in California.

Aricaras, or *Rikarees*, dwell on the plains of the Upper Missouri, between 46° and 47° N. lat. They are skilful horsemen, were allied with the Mandans and Minatarees, and hostile to the Sioux, which are the neighbouring tribes. Their habitations are formed, in a conical shape, of wooden frames interlaced with osiers; and they amount to about 3000.

Assinaboins, or stone-boilers, so called because they cook their food by inserting hot stones successively in a pit filled with water till the water boils. They inhabit the plains along the base of the Rocky Mountains, around the upper part of the Missouri, at its junction with the Yellow-sand river. Their number is supposed not to exceed 7000. They are horsemen, and use the gun with effect; they are a branch of the Sioux, and are usually allied with the Crees and the Ojibbeways, and at variance with the Blackfeet.

The *Beaver* Indians, of whom little is known, dwell about the forks of the Mackenzie river, west of Bear Lake. Their district is a wide one. With the *Hare* Indians and *Loucheux*, who extend along the same river to the north, it reaches from about 61° to 70° N. lat., where they are bounded by the Esquimaux. Their numbers are unknown.

The *Blackfeet* is one of the most powerful tribes of the Rocky mountains; it includes several minor tribes, as the Blood Indians, the Surcees, Grosventres, Cotonnois, &c., and their numbers are estimated at 20,000. Wilks ('Narrative of the United States Exploring Expedition, 1838 to 1842') thinks the number exaggerated; but Catlin, who was among them, estimates the number, including all the sub-tribes (which, however, he thinks are improperly classed as Blackfeet), at 23,000. The Blackfeet proper inhabit the district around the sources of the Missouri, but the Blood Indians extend to the roots of the Rocky Mountains on the west. The Blackfeet are of middle stature and robust make; are good horsemen, brave, and almost continually at war with one or other of the surrounding tribes.

Bonacks, or *Bannacks*, are widely scattered around the Snake river, and are neighbours and foes of the Blackfeet. Their numbers are small, but they are brave and enterprising, and accustomed to the use of fire-arms.

Camanchees, with the *Pawnee Picts* and a few minor tribes, such as the Kioways and Wicos, occupy a great portion of Texas about the Washita river, and the head waters Rio del Norte and the Arkansas river, the Pawnees extending to northern California. They amount together to about 19,000 souls, have large numbers of horses, are daring and expert riders, but, unlike most of the tribes, are not active on their feet. The women cultivate maize and a few other vegetables; the men are all warriors, and have maintained many contests with the American settlers. The Kioways are said to be a handsomer race than the Camanchees, and to speak a different language, but they are closely allied in manners.

Cherokees. [CHEROKEES, in GEOG. DIV.]

Chinooks is apparently a general name for a number of tribes that inhabit British Columbia, in the neighbourhood of the Oregon. They are short, bow-legged, with wedge-like heads, produced by compressing the skulls of their infants, high cheek-bones, long hair, aquiline noses, and of a light copper-colour. They live chiefly on fish. The *Chillcoatans* are found about Fraser's river. Other sub-tribes are the Callapayas, Cathlamahs, Clatsops, Klackatacks, Wahkiacums, and Wallawallas, the whole amounting to between 3000 and 4000. They live principally by fishing, the salmon caught in the Columbia river forming the chief part of their food. This they prepare by pounding the salmon, pressing the flesh between mats, and drying it, in which state it will keep good for three or four years.

The *Chicksaws* and *Choctaws* were located in Mississippi, and numbered about 10,000 souls, but they have been transferred by the United States government to the district west of the Mississippi, where they now remain, reduced in number.

Cheyennes number about 2000; they are a branch of the Shaways, and were originally located in Wisconsin, whence they were driven by the Sioux, and now dwell about the Cheyenne river, towards the sources of the Upper Missouri. They are a tall and handsome race, possess many horses, and the women raise some corn and other vegetables.

Crees and *Chippeways* constitute at present one of the most numerous and most widely extended of the aboriginal nations which inhabit the interior of North America, amounting to upwards of 10,000. The Crees, formerly called by the French Knistineaux, inhabit the shores of Hudson's Bay from Moose river, which falls into the south-western

corner of James Bay, to the mouth of Churchill river (about 59° N. lat.), and hence they extend westward to the Athabasca lake, and to the plains which lie betwixt the forks of the Saskatchewan, near Carlton House. They do not extend to the Rocky Mountains, the plains lying along the base of this range being in possession of a branch of the Assineboin Indians, who are of the Sioux stock, and speak the language of the Iroquois or Hurons. The Chippeways inhabit the country about Lakes Michigan, Huron, and Superior. But it seems that many other tribes belong to the same stock as the Crees; for all the nations which are within the limits of the United States north of the Ohio and east of the Mississippi speak languages which may be considered only as dialects of that spoken by the Crees and Chippeways. [ALGONQUINS, in GEOG. DIV.] (See 'Sir G. Simpson and North American Indians,' Kane.) The *Lennapi*, one of these tribes, have a tradition amongst them, that "their ancestors, coming from the westward, took possession of the whole country from the Missouri to the Atlantic, after driving away or destroying the original inhabitants of the land, whom they termed Alligewi. In this migration and contest, which endured for a series of years, the Mengwe or Iroquois kept pace with them, moving in a parallel but more northern line, and finally settling on the banks of the St. Lawrence and the great lakes from whence it flows." (Richardson in 'Franklin's First Journey.') The Crees, like the other tribes of North America, live upon the produce of the chase and the fisheries in the numerous lakes and rivers by which their country is watered. No kind of agriculture has been introduced among them, as among those tribes that inhabit the southern portions of the United States. This is chiefly to be ascribed to the general sterility of the countries which they inhabit, and partly to the rigour of the climate. Even in the European settlements no attempt to sow and plant has been made north of Carlton House, on the Saskatchewan, and at the latter place only on a small scale. The hardships to which their manner of life frequently exposes them, and the want of food for some weeks together, sometimes compel them to commit cannibalism; and Captain Back relates instances of this, and others of their abandoning the old and infirm. Instances of this kind are on record, even of parents having fed on their own children; but these extreme cases are of rare occurrence. They commonly evince a strong affection for their offspring, and bewail for a length of time the loss of their relations. Europeans are very little acquainted with the language of the Crees. M'Keevor has added a short vocabulary to his voyage. Dr. Richardson collected a copious and valuable vocabulary, which is still unpublished. Mr. J. Howse of Cirencester, who was in the service of the Hudson's Bay Company for twenty years, has prepared, under the sanction of the London Geographical Society, a grammar of the Cree language. (Back's 'Narrative of the Arctic Land Expedition,' in 1833, 1834, and 1835.)

Creeks were, at the beginning of the present century, one of the most powerful native tribes within the limits of the United States of America. They occupied nearly all the countries lying north of 31° N. lat., between the Flint river, the eastern branch of the Chatahoochee, and the Tombigbee or western branch of the Mobile river, and numbered nearly 24,000 souls. Their wars with the United States were uniformly unsuccessful, and they have now been, together with the Cherokees and Choctaws, transported to a district west of the Mississippi, a large tract of country having been ceded to them by the United States.

Crows is the name of the tribe inhabiting the country in the recesses of the Rocky Mountains, between the Wind River Mountains and the river Platte, the upper part of the Missouri near its junction with the Yellow-Stone river to the Big-Horn river on the south-east. They number nearly 4000, are noted for their predatory habits, horses being especially the objects of their plunder, to procure which they extend their excursions for long distances on each side of the mountains, and are in constant hostility with all the surrounding tribes.

The *Hurons* between Lakes Huron and Ontario; the once-powerful *Iroquois*, who extended on both sides of the Mississippi; the *Mohicans*, who were at home in Connecticut; the *Oneidas* and *Onondagas*, of New York; the *Shawanoes* of Pennsylvania, to which may be added the *Delawares* from Delaware Bay, are now all but extinct. The last-named two have both possessed Wyoming at different times, and the bones of their ancestors repose on "Susquehanna's banks." Except the *Delawares*, *Shawanoes*, and *Oneidas*, of whom fragments have been located west of the Mississippi, and have become in some degree agriculturists, only individuals remain. The Iroquois language, however, is said to be yet widely spoken.

The *Ioways*, who only number 1100, live between the forks of the Grand River and those of the River des Moines on the west of Illinois. They are probably a branch of the Sioux, whose territory adjoins them.

The *Kickapoos* are a small tribe of about 800, living near the south end of Lake Michigan, in Illinois.

The *Mandans* were one of the most curious tribes. They were located, prior to 1840, on the west bank of the Missouri, 1800 miles above St. Louis, and 200 below the mouth of the Yellow Stone. Number, about 2000. They did not bury, but placed their dead on scaffolds, there to moulder and decay. When the scaffolds fell, and the flesh had decayed, the skulls were placed on the ground in circles, and the other bones were buried. The colour of the hair and complexion was various: the hair of females in youth being often of a silvery gray, fine, and

silky. They swam not like Europeans, but, throwing the body on one side, the hand was drawn through the water inward under that side, while the other hand reached as far forward as possible, out of the water, till the lower stroke was completed; then the side was changed, and the other hand was drawn through the water. They were polygamists; as the wars carried off so many men, there were often three females to one male in a tribe. They raised corn (Indian), pumpkins, &c., all the labour being performed by the women. They have been since exterminated by the small-pox; only thirty, it is stated by Catlin, having survived, and these were killed by the Sioux. A smaller tribe, *Minatarees*, were their allies, or dependents, and have shared the same fate.

The *Micmacs* are a small tribe still existing in Nova Scotia. They exhibited themselves and their war-dance to the Prince of Wales on his visit to America in 1860.

The *Monquois* or *Monkey* Indians, inhabit a district south-west of Lake Utah. Little is known of them, but they are said to be as light-coloured as Spaniards, neat in their dress, decorous in their manner, and their women to be beautiful. A theory has been raised that they are the descendants of the Welsh colony led by Madoc, though others suppose the Mandans to have a better claim. Not enough is known of either to warrant a conclusion, and further acquaintance will probably strip them of some of their favourable attributes.

The *Ojibbeways* dwell east of the Rocky Mountains, round the upper part of the Missouri at its junction with the Yellow-Stone. They are undoubtedly a branch of the Chippeways; and are amongst the best-formed, and the most picturesque in their dress of any of the Indian tribes. They live in a country well-stocked with game, are of robust make, and of middle stature. They number not more than 1500.

The *Osages*, a powerful and warlike tribe, are found chiefly about the Osage and White rivers, on the western borders of Missouri and Arkansas. They hunt the buffalo, but raise some maize. The *Kansas*, their neighbours, may be a part of the same tribe, as they resemble each other closely, the Kansas ranging along the river of that name and its tributary streams. Together they number upwards of 5000.

The *Pawnees* (who are not to be confounded with the Pawnee Picts, mentioned before) are a numerous tribe of 16,000 souls. They dwell in the plains between the Platte or Nebraska river and the Missouri, in lat. 42° N. and long. 25° to 28° W. They are horsemen, and depredators.

The *Potawattomies* and *Miamis* roam about the district west of Indiana, on the Wabash River, south of Lake Michigan, and number about 7000.

Sacs and *Foxes* inhabit the district west of Wisconsin. They are brave and dangerous, and number upwards of 5000 souls, but they sold their hunting-grounds, 256,000 acres, on the Ioway River, and migrated.

The *Seminoles* were once a powerful tribe in Florida, and gave much trouble to the State. They still amount to 5000 in number, but have been removed by the United States government.

The *Sioux* or *Dacotas* are by far the most numerous race of the Indian tribes, numbering it is said 27,000 souls. Their territory is a wide one, extending from about 40° 30' to 42° 15' N. lat., and from the Mississippi to the Rocky Mountains west. The principal settlement is at the mouth of the Teton river on the Upper Missouri. They are horsemen, well armed, constantly in hostility with the fur-hunters of the west, and with most of the neighbouring tribes, especially with the Blackfeet.

The *Snakes*, or *Shoshonees*, living in the neighbourhood of the Snake river are one of the principal tribes of the southern or American portion of Columbia. They probably amount to about 20,000 souls. The Snakes are the remains of a tribe driven by the Blackfeet from their old possessions on the Missouri. A part of them are called *Shooshooks* or *Diggers*, a degraded race, living on wild roots, whence their name. They are all a poor and depressed race, living chiefly on fish, and often subjected to great privation. Another tribe, the *Flatheads*, higher up among the roots of the Rocky Mountains, between Lewis river and Clarke's river, a much finer race of men, do not artificially flatten the skull. They are associated with the *Nez Perce*, and the *Clamets* or *Tootonez*, on the borders of North California. They are hunters and fishers, possessed of a few horses, but live during the winter chiefly on roots. They number probably altogether about 8000 souls.

The *Winnebagoes* and *Menemonies* dwell in the country east of the Mississippi, and west of Green Bay, about the Wisconsin and Fox rivers, but chiefly at the Prairie des Chiens. They were once powerful tribes, but are now reduced, and number about 4000 souls.

The government of the United States have removed the greater part of the native Indians who were dwelling within their dominions to a territory west of the states of Missouri, Arkansas, and Louisiana; extending thence to Texas and the Rocky Mountains. From north to south they are located in the following order:—the Kickapoos, on an affluent of the Missouri, in about N. lat. 41°; the Delawares, Shawnees, Kaskaskias, Piankeshaws and Weahs, Oneidas, Tuskaruras and Quapaws, Senecas, Shawnees, Cherokees, Creeks, Seminoles, Choctaws, and Chickasaws, in about N. lat. 32°. In 1853 the Commissioner of Indian Affairs estimated the total number of Indians in the United States at 400,764, of whom 271,930 were in California, Oregon, Texas and New Mexico. At that date the Indians of the old

states had decreased 532 from the number in 1828. [INDIAN TERRITORY, in GEOG. DIV.]

There still remain a great number of tribes, consisting of small numbers, who chiefly inhabit the same regions. It must be borne in mind also that the population given is only an estimate made at various times, and is almost constantly decreasing. Even the places they inhabit can only be vaguely indicated, as they are constantly trespassing on each other's grounds, which are much intermixed, and the weaker are uniformly dispossessed by the stronger races, and are then forced to seek other grounds where they can more safely remain. The recent extensive emigrations also to the gold regions of California, that of the Mormons and others to Utah, and more lately the passage of many to the English settlement on Fraser's river in Columbia, have created highways through the passes of the Rocky Mountains, lessening the dangers from the predatory habits of the Indians, still more weakening their powers of offence, and gradually reducing their numbers.

NOSOLOGY (from *νόσος* and *λόγος*) is the term applied to the classification and arrangement of diseases. It was early found in the observation of the symptoms of disease, that many of them recurred again and again, and this led to the assigning to such groups of symptoms particular names. Thus we find that the term fever was early applied to designate a certain set of symptoms, and, as any of these symptoms preponderated, the fever obtained a specific name, as putrid fever, petechial fever, &c. But not only were symptoms had recourse to for the purpose of distinguishing peculiar forms of fever, but the causes and the locality were frequently employed; thus marsh, jail, hospital, and other fevers have been described. In this way the materials were early accumulated for the formation of a system of nosology. It was not, however, till comparatively modern times, that anything like a scientific system of arrangement was proposed. One of the earliest of these was that of Sauvages, who, taking the most prominent symptoms of diseases as his guide, divided them into ten great classes which he named *Vitia*, *Febres*, *Phlegmasiæ*, *Spasmi*, *Anhelationes*, *Debilitates*, *Dolores*, *Vesaniæ*, *Fluxus*, and *Cachexiæ*. Under these classes were arranged various orders: thus, under the first class *Vitia*, he arranged the orders, *Maculæ*, *Efflorescentiæ*, *Phymata*, *Excrecentiæ*, *Cystides*, *Ectopiæ*, *Plagæ*. The order *Maculæ* was divided into the diseases *Leucoma*, *Vitiligo*, *Ephelis*, *Gutta rosea*, *Nævus*, and *Ecchymoma*. This classification of diseases was followed by those of Linnæus, Vogel, Sager, and Macbride, but in their arrangements they all recognised the same principle of classification as Sauvages, and made their division of diseases to depend on the greater or less prominence of particular symptoms. All these systems, were, however, supplanted by that of Cullen, which he promulgated in the second edition of his '*Synopsis Nosologicæ Methodicæ*.' The following plan will give an idea of its structure:—

CLASS I.—PYREXiE.

ORDER I.	21 Rheumatismus
FEBRES.	22 Odontalgia
§ 1. <i>Intermittentes</i> .	23 Podagra
1 Tertianæ	24 Arthropousis
2 Quartana	ORDER III.
3 Quotidiana	EXANTHEMATA.
§ 2. <i>Continuæ</i> .	25 Variola
4 Synocha	26 Varicella
5 Typhus	27 Rubeola
6 Synochus	28 Scarlatina
ORDER II.	29 Pestis
PHLEGMASIE.	30 Erysipelas
7 Phlogosis	31 Miliaria
8 Ophthalmia	32 Urticaria
9 Phrenitis	33 Pemphigus
10 Cynanche	34 Aphtha
11 Pneumonia	ORDER IV.
12 Carditis	HÆMORRHAGIE.
13 Peritonitis	35 Epistaxis
14 Gastritis	36 Hæmoptysis
15 Enteritis	37 Hæmorrhoids
16 Hepatitis	38 Menorrhagia
17 Splenitis	ORDER V.
18 Nephritis	PROFLUVIA.
19 Cystitis	39 Catarrhus
20 Hysteritis	40 Dysenteria

CLASS II.—NEUROSES.

ORDER I.	ORDER II.
COMATA.	ADYNAMIE.
41 Apoplexia	43 Syncope
42 Paralysis	44 Dyspepsia

- 45 Hypochondriasis
46 Chlorosis

ORDER III.

SPASMI.

- 47 Tetanus
48 Convulsio
49 Chorea
50 Raphania
51 Epilepsia
52 Palpitatio
53 Asthma
54 Dyspnœa
55 Pertussis

- 56 Pyrosis
57 Colica
58 Cholera
59 Diarrhœa
60 Diabetes
61 Hysteria
62 Hydrophobia

ORDER IV.

VESANIE.

- 63 Amentia
64 Melancholia
65 Mania
66 Oneirodynia

CLASS III.—CACHEXIÆ.

ORDER I.

MARCORES.

- 67 Tabes
68 Atrophia

ORDER II.

INTUMESCENTIÆ.

§ 1. *Adiposæ*.

- 69 Polysarcia

§ 2. *Flatuosæ*.

- 70 Pneumatosis
71 Tympanites
72 Physometra

§ 3. *Aquosæ*.

- 73 Anasarca
74 Hydrocephalus

- 75 Hydrorachitis
76 Hydrothorax
77 Ascites
78 Hydrometra
79 Hydrocele

§ 4. *Solidæ*.

- 80 Physconia
81 Rachitis

ORDER III.

IMPETIGINES.

- 82 Scrofula
83 Syphilis
84 Scorbutus
85 Elephantiasis
86 Lepa
87 Framboesia
88 Trichoma
89 Icterus

CLASS IV.—LOCALES.

ORDER I.

DYÆSTHESIÆ.

- 90 Caligo
91 Amaurosis
92 Dysopia
93 Pseudoblepsis
94 Dysecœa
95 Paracusis
96 Anosmia
97 Agheusia
98 Anæsthesia

ORDER II.

DYSOREXIÆ.

§ 1. *Appetitus erronei*.

- 99 Bulimia
100 Polydipsia
101 Pica
102 Satyriasis
103 Nymphomania
104 Nostalgia

§ 2. *Appetitus deficientes*.

- 105 Anorexia
106 Adipsia
107 Anaphrodisia

ORDER III.

DYSCINESIÆ.

- 108 Aponia
109 Mutitas
110 Paraphonia
111 Psellismus
112 Strabismus
113 Dysphagia
114 Contractura

ORDER IV.

APOCENOSES.

- 115 Profusio
116 Ephidrosis
117 Epiphora

- 118 Ptyalismus
119 Enuresis
120 Gonorrhœa

ORDER V.

- 121 Obstipatio
122 Ischuria
123 Dysuria
124 Dyspermatusmus
125 Amenorrhœa

ORDER VI.

TUMORES.

- 126 Aneurisma
127 Varix
128 Ecchymoma
129 Scirrhus
130 Cancer
131 Bubo
132 Sarcoma
133 Verruca
134 Clavus
135 Lupia
136 Ganglion
137 Hydatis
138 Hydarthrus
139 Exostosis

ORDER VII.

ECTOPIÆ.

- 140 Hernia
141 Prolapsus
142 Luxatio

ORDER VIII.

DYALYSES.

- 143 Vulnus
144 Ulcus
145 Herpes
146 Tinea
147 Psora
148 Fractura
149 Caries

It was the simplicity of this system which recommended it to general adoption, and which has caused it to exercise so great an

influence over other systems of pathology. At the same time it will be seen that this and the previous systems are purely artificial, and frequently bring together diseases of a very dissimilar character. Such systems have also led to the impression that diseases have a character as definite as the objects of natural history, and that a species in the one can be as easily defined as the species of another. But it becomes evident, after a little inquiry, that, with the exception of those diseases that depend on a specific contagion, no part of the idea of a species as applied to plants or animals can be made use of to designate particular diseases.

With the progress of a sound knowledge of physiology and pathology, many attempts have been made to give a more natural arrangement of diseases than that of Cullen. Dr. Mason Good divided diseases into the following six classes:—

- CLASS I.—*Caliaca*. Diseases of the digestive functions.
 CLASS II.—*Pneumatica*. Diseases of the respiratory function.
 CLASS III.—*Hæmatica*. Diseases of the sanguineous function.
 CLASS IV.—*Neurotica*. Diseases of the nervous function.
 CLASS V.—*Genetica*. Diseases of the sexual function.
 CLASS VI.—*Ec critica*. Diseases of the excrement function.

This system, however successful it may be regarded in its primary divisions, was too technical in its details to be very generally employed. One of the most simple of natural classifications founded on pathological distinctions is that of Pinel, who divides diseases into fevers, inflammations, hæmorrhages, neuroses, and organic affections.

The necessities of the statist have introduced a nosology in England, which in a little time is likely to supplant all others. Already parts of this system have been adopted by medical writers, and in one instance, an entire treatise on medicine has been founded on it, so that although it has not yet found its way into the bulk of medical treatises, there can be no doubt that it is destined to exercise a considerable influence in the classification of disease. The system is that of Dr. William Farr, and is the one adopted by the Registrar General in his weekly, quarterly, and annual reports on the mortality of London and England.

CLASS I.—ZYMOTIC DISEASES.

Diseases that are either epidemic, endemic, or contagious, induced by some specific body, or by the want of food, or by its bad quality.

ORDER I.

MIASMATIC DISEASES.

Small pox
 Varioloid disease
 Chicken pox
 Miliaria
 Measles
 Scarlatina
 Hybrid of Measles and Scarlet fever
 Dengue
 Quinsy
 Diphtheria
 Mumps
 Croup
 Hooping cough
 Typhoid fever
 Relapsing fever
 Typhus fever
 Erysipelas
 Erythema
 Hospital gangrene
 Pyæmia
 Metria
 The Plague
 Carbuncle
 Boil
 Influenza
 Dysentery
 Diarrhoea
 Cholera
 Yellow fever
 Remittent fever
 Crimean fever
 Hong Kong fever, &c.
 Ague
 Rheumatism

ORDER II.

ENTHETIC DISEASES.

Syphilis, primary

Syphilis, secondary

Gonorrhoea

Leprosy (including the Greek elephantiasis, and the leprosy of Moses)

Yaws

Pellagra

Radesyge

Purulent ophthalmia

Glanders

Hydrophobia

Nerunica

Malignant pustule

ORDER III.

DIETIC DISEASES.

Famine Fever

Scurvy

Purpura

Rickets

Bronchocele

Cretinism

Alcoholism

Delirium tremens

ORDER IV.

PARASITIC DISEASES.

Thrush

Porrigo

Scabies

Phthiriasis

Worms

a Hydatids

b Tape worms

c Strongylus gigas

d Round worm

e Thread worm

f Guinea worm

CLASS II.—CONSTITUTIONAL DISEASES.

Sporadic diseases affecting several organs, in which new morbid products are often deposited, sometimes hereditary.

ORDER I.

DIATHETIC DISEASES.

Gout
 Anæmia
 Dropsy
 Cancer
 Melanosis
 Lupus
 Canker

CLASS III.—LOCAL DISEASES.

Sporadic diseases in which the functions of particular organs or systems are disturbed or obliterated with or without inflammation; sometimes hereditary.

ORDER I.

BRAIN DISEASES.

Meningitis
 Encephalitis
 Cephalitis
 Myelitis
 Apoplexy
 Paralysis
 Shaking Palsy
 Chorea
 Delirium tremens
 Mania
 Monomania
 Dementia
 Epilepsy
 Hysteria
 Tetanus
 Convulsions
 Laryngismus
 Neuralgia
 Tic-doloureux
 Neuroma

ORDER II.

HEART DISEASES.

Carditis
 Pericarditis
 Endocarditis
 Valvular disease of heart
 Hypertrophy of heart
 Atrophy of heart
 Fatty degeneration of heart
 Aneurism of heart
 Aneurism of aorta
 Angina pectoris
 Fainting
 Arteritis
 Atheroma
 Phlebitis
 Varicose veins

ORDER III.

LUNG DISEASES.

Hæmoptysis
 Laryngitis
 Laryngismus
 Bronchitis
 Pleurisy
 Hydrothorax
 Empyema
 Pneumothorax
 Apoplexy of lungs
 Pneumonia
 Pleuro-pneumonia
 Asthma
 Emphysema of lungs
 Grinders' asthma
 Miners' asthma
 Colliers' phthisis

ORDER IV.

BOWEL DISEASES.

Glossitis
 Stomatitis
 Pharyngitis
 Esophagitis
 Gastritis
 Enteritis
 Peritonitis

Mortification
 Dry gangrene

ORDER II.

TUBERCULAR DISEASES.

Scrofula
 Mesenteric tuberculosis
 Tubercular peritonitis
 Phthisis
 Hydrocephalus

ORDER V.

KIDNEY DISEASES.

Nephritis
 Ischuria
 Diuresis
 Bright's disease
 Albuminuria
 Diabetes
 Stone
 Gravel
 Hæmaturia
 Cystitis

ORDER VI.

GENETIC DISEASES.

Varicocele
 Orchitis
 Hydrocele
 Hysteritis
 Uterine tumours
 Ovarian tumours
 Ovarian dropsy

ORDER VII.

BONE AND MUSCLE DISEASES.

Synovitis
 Ostitis
 Exostosis
 Brittle bones
 Soft bones
 Spinal curvature
 Caries
 Necrosis
 Muscular atrophy

ORDER VIII.

SKIN DISEASES.

Roseola
 Urticaria
 Eczema
 Herpes
 Pemphigus
 Rupia
 Ecthyma
 Impetigo
 Acne
 Mentagra
 Lichen
 Prurigo
 Psoriasis
 Pityriasis
 Icthyosis
 Phlegmon
 Whitlow

CLASS IV.—DEVELOPMENTAL DISEASES.

Special diseases, the incidental result of the formative, reproductive, and nutritive processes.

ORDER I.

DEVELOPMENTAL DISEASES OF CHILDREN.

Stillborn
• Premature birth
Atelectasis
Malformation
Cyanosis
Spina bifida
Imperforate Orifices
Idiotcy
Congenital deaf-dumbness
Teething

ORDER II.

DEVELOPMENTAL DISEASES OF WOMEN.

Chlorosis
Childbirth
Paramenia
Climacteria

ORDER III.

DEVELOPMENTAL DISEASES OF OLD PEOPLE.

Old age

ORDER IV.

DISEASES OF NUTRITION.

Atrophy
Asthenia

NOTARY. This word is derived from the Roman name *notarius*, a person who was so called from his taking down in notes or writing (*notæ*) the words of a speaker. The *notarii* were in fact short-hand writers, for it is clear from many passages of ancient writers that they used symbols of abbreviation.

"Hic et scriptor erit felix cui litera verbum est,
Quique notis linguam superet cursumque loquentis,
Excipiens longas nova per compendia voces."

Manilius, 'Astronom.'

"Currant verba licet, manus est velocior illis,
Nondum lingua suum, dextra peregit opus."

Martial, 'Epig.,' xii. 208.

It seems that they were also employed to take down a man's will in writing. The *notarii* were often slaves. The word is also sometimes used to designate a secretary to the princeps or emperor. (Ausonius, *Epig.*, 136; Gregor. Nazianz., in the letter inscribed τῷ Νοταρίῳ; Augustine, lib. ii., 'De Doctrinâ Christianâ,' Dig. 29, tit. 1, sec. 40; Lampridius, *Alex. Sev.*, 28; see also the references in Faccioliati, *Notarius*.)

In the fourth century, the *notarii* were called *Exceptores*, and were employed by the governors of the Roman provinces to draw up public documents. But the persons mentioned under the later Roman law, who corresponded most nearly to the modern notary, are called *tabelliones*. Their business was generally to draw up contracts, wills, and other instruments. The forty-fourth Novel treats specially of them (περὶ τῶν συμβολαιογραφῶν); and they are spoken of in various other parts of the Novels, and in the Code. (*Cod.* xi. tit. 53, &c.) It appears clear that as the word *notarius* is the origin of the modern term notary, so the *tabellio* is the person from whom were derived the functions of the modern notary public.

It is impossible to say when persons under the name and exercising the functions of notaries were first known in England. Spelman cites some charters of Edward the Confessor as being executed for the king's chancellor by notaries. (*Gloss. tit. Notarius*.) "Notaries," are mentioned with "procurators, attornies, executors, and maintainours," in the stat. of 27 Edward III. c. 1. They were officers or ministers of the ecclesiastical courts, and may therefore have been introduced into this country at a very early period. It is generally supposed that the power of admitting notaries to practice was vested in the archbishop of Canterbury by the 25 Hen. VIII. c. 21, s. 4. The term of service and the manner of admission to practice are now regulated by the 41st Geo. III. c. 79, which prescribes that no person in England shall act as a public notary or do any notarial act unless he is duly sworn, admitted, and enrolled in the court wherein notaries have been accustomed to be sworn, admitted, and enrolled. He must also have been bound by contract in writing to serve for seven years to a notary, or to a scrivener using his art and mystery according to the privilege and custom of the city of London. Persons who act as notaries for reward, without being properly admitted and enrolled, are liable for every offence to forfeit the sum of 50*l.*; but British consuls abroad are empowered to perform notarial acts (6th Geo. IV. c. 87, s. 20). The licence or commission for acting as a notary in England requires a stamp duty of 30*l.*, and in Scotland one of 20*l.* The annual certificate is the same as for attornies. By 3 and 4 Will. IV. c. 70, the provisions of 41 Geo. III., so far as relates to the apprenticeship for seven years, are confined to London and Westminster, Southwark, and a circuit of ten miles from the Royal Exchange in London; and the master of the Court of Faculties of the archbishop of Canterbury is empowered to appoint and admit any attorney, solicitor, or proctor, not residing within the above-mentioned limits, to be a notary public, to practise within any district in which he shall see good reason for making such appointment.

The original business of notaries was to make all kinds of legal instruments; they are often spoken of in former times as the persons

who made wills (Shepherd's *Touchstone*, vol. ii. 407, Preston's ed.); but the attorney and conveyancer have now got possession of this part of their business. In practice their business is now limited to the attestation of deeds and writings for the purpose of making them authentic in other countries, but principally such as relate to mercantile transactions. It is also their business to make protests of bills of exchange. They also receive and take the affidavits of mariners and masters of ships.

NOTATION. [SYMBOLS.]

NOTATION, CHEMICAL. [CHEMICAL FORMULÆ.]

NOTATION, in music, signifies the method whereby the pitch, or tune, and duration of musical sounds are represented, and by which definite periods of silence, called *rests*, are marked. It is to music what letters and punctuation are to language.

To show the pitch, the Greeks used the letters of their alphabet, placed in various positions. [MUSIC.] The Romans had recourse to the majuscules of their own alphabet for the same purpose, till the latter part of the 6th century, when St. Gregory, or Pope Gregory I., employed the first seven capital Roman letters for the first septenary, beginning with the A answering to the lowest space in our base clef. For the next ascending septenary he used the corresponding small letters; and the third he denoted by the same small letters doubled. Example, explained in modern notation:—

Guido, early in the 11th century, introduced, it is commonly supposed, the use of points instead of letters, which he placed on parallel lines, giving names to the latter by means of letters, which have since been gradually transformed into those signs called clefs. [GUIDO, in BIOG. DIV.; GAMUT; CLEF.] The dots, however, of Guido only marked the degrees of high and low; to Franco of Cologne we are indebted for characters which at once denoted both the tune and time of the sounds. [MUSIC.] Of these he invented four, and their rests; namely, the—

These were valued or measured by the semibreve. The breve was equal to two semibreves, the long to four, and the large to eight. [LONG, &c.] The invention of the minim, crotchet, quaver, and semiquaver, is ascribed to John de Muris, a doctor of the Sorbonne, who made this important addition to notation, and also originated certain characters determining the measure, in the year 1338. The demisemiquaver first appeared in the 17th century, and about the middle of the last was divided into halves. Latterly it has been subdivided into quarters, and even into eighths, most unnecessarily, and greatly to the perplexity of the performer, and, consequently, to the detriment of the art, by wantonly, and with mischievous affectation, throwing difficulties in the way of its attainment.

We have not been able to ascertain at what time the sharp and flat were brought into use. The sharp was at first square in form, according to Butler ('Principles,' &c., 1636). The flat was always a small *b*. The natural is, comparatively, of modern date. Till towards the close of the 17th century, the secondary use of the sharp was to contradict the flat, and of the flat to contradict the sharp. The natural, introduced at nearly the same time, relieved the two other characters from part of their duty. In the printed score of Lully's opera, 'Persée,' dated 1684, the natural does not appear; nor even in his 'Armide,' published in 1710. In Purcell's 'Diocletian' (1691) sharps and flats contradict each other; but the natural is occasionally used. [SHARP; FLAT; NATURAL.] The grouping of quavers, &c., by means of ligatures, or ties, joining the stems, is also one of the improvements made in the latter half of the 17th century. It does not seem to have been practised in 1653, when Lawes printed his 'Ayres,' &c. In Lully's 'Proserpine' (1680) we find quavers tied at the bottom of their stems, in groups of four, but semiquavers are all detached. The use of bars became general about the middle of the 17th century, though this mode of division was partially adopted much earlier. [BAR; ABBREVIATIONS; DOT; NOTE; TIME.]

NOTE, in music, a character which, by its place on the staff, represents a sound, and by its form determines the time or continuance of such sound. There are six notes in ordinary use—the semibreve, minim, crotchet, quaver, semiquaver, and demisemiquaver. To these may be added the breve, yet met with in sacred music; and the half-demisemiquaver, much used, and often unnecessarily, by the moderns. [BREVE; SEMIBREVE, &c.] The value or length in time of the semibreve may be considered as unity: the minim is $\frac{1}{2}$, the crotchet $\frac{1}{4}$, the quaver $\frac{1}{8}$, the semiquaver $\frac{1}{16}$, and the demisemiquaver $\frac{1}{32}$. Hence is formed the following *Table of Proportions*, as it is denominated:—

And hence it will also appear, that one minim is equal to two crotchets, &c.; one crotchet to two quavers, &c., &c.

The word *note* is frequently used as a synonym of sound; thus we say a high, low, loud, or soft *note*, or the *note* A; a flat *note*, &c. Some confusion occasionally arises out of this double meaning; but the musical nomenclature is very imperfect, and any attempt to improve this or any other branch of the art meets with little support from its professors.

NOTHING. In the article **INFINITE** will be found as much upon this word as will enable us to dispense with the consideration of the symbol 0, as the limit approached but never attained by the continual diminution of magnitude.

Among the terms used in mathematical language are *nothing*, *cipher*, and *zero*. The etymologies of the two latter terms are explained under those heads: their meanings are somewhat different. The first word, *nothing*, implies the absence of all magnitude, but its occurrence denotes either that magnitude did exist, or might have existed, or does exist, under similar circumstances in other problems, or in the same problem under different points of view. Were it not for this, the word would be useless: thus we do not consider it necessary to speak of 20*l.* generally as twenty pounds, no shillings, no pence, and no farthings. But if this 20*l.* had been the amount of a number of sums, the symbol £20 0 0 would be useful as indicating that the results of an operation (addition) had left no quantities in places where beforehand quantity might have been expected. The term *unity* would have been useless in the same manner, except as a tacit reference to other units; anything we please is *one* of its kind, and accordingly the indefinite article (*a* or *an*), which is certainly *one* in etymology, has lost its definite monadic signification, because such signification is useless. This point is of some importance to the mathematician, as justifying a use of the symbol 0 where it might seem redundant. The 0 and 1 are frequently useful as symbols of distinction where they are not wanted as symbols of operation: in like manner, in common language, the simple phrase "*one* ox and *no* sheep," though it implies no more of positive conception than the more simple phrase "*an* ox," may be a proper description where the second would be no such thing.

The *cipher* is 0 considered in a purely arithmetical point of view, as the mode of denoting a blank column intervening between, or following, or even preceding, columns which contain significant numbers.

The term *zero* considers 0 rather as a starting point of magnitude than as the symbol for the recognition of absence of all magnitude, and really denotes, not the entire absence of magnitude, but the arbitrary determination to reckon all magnitudes by their excess or defect from a certain zero magnitude. Thus the zero point of the thermometer does not mean that shown when there is no temperature, but a certain temperature, that of freezing water; and degrees above and below zero indicate excesses or defects of temperature above or below that standard. It is then perfectly proper to say that ten degrees below zero is a lower temperature than five degrees, and that both are less than zero. Whenever magnitude is considered in connection with modifications, the zero and even the nothing of such magnitude may require to be considered with similar modifications, even though all absolute magnitude is lost. Straight lines, for example, admit of consideration with reference not only to their lengths, but also to their positions and directions. Let the straight lines diminish each by an approach of one extremity towards the other, and position and direction still always distinguish each line from the others, though all be of the same linear magnitude (length); when the one extremity actually reaches the other, length is destroyed, but one indication of position still remains, the fixed extremity, or what was the fixed extremity so long as the line had length. Different points (*nothings* of length) still tell something about the positions of the different lines which left them; and there are as many *nothings* of length (distinguishable) as there are different points in space. These zeros, as it might be proper to call them, are of most essential consequence, as *zeros*, in the complete method of connecting the explanations of symbols in algebra (in the widest sense of the term) with those of the restricted or arithmetical sense. [ALGEBRA.] All direction however has disappeared when a line is reduced to a point; and considerations arising out of this, the principles of which appear in **FRACTIONS**, **VANISHING**, will be applied in the article **TANGENT**.

It might seem as if, in the consideration of the term *zero*, we had commenced an explanation of negative quantities, and had obtained a

justification of the phrase *less than zero*, if not of *less than nothing*. This may be true to a certain extent, too limited however for the purposes of algebra, and not sufficiently expressive of the actual meaning of the words. When the distinction of positive and negative quantities is explained and adopted, the terms greater and less are no longer used in their simple arithmetical meaning, but take a wider signification, such as will allow old theorems of arithmetic to remain true under the same phraseology as before. After an express extension of signification has been accorded to these terms, it is not wonderful that uses of them should be perfectly allowable which could not be made if we retained the old significations. Those who use the extended meanings, without fully understanding and admitting them, will make a mystery of algebra: those who refuse to make the extensions, and yet charge others who do not refuse with falling into all the absurdities which extended uses without extended meanings present to *themselves*, are precisely in the condition of the honest tar who asserted that the French were such fools as not to know the difference between a cabbage and a shoe (*chou*). But those again who, professing to use extended meanings, do not take care to make their logic conformable to them, but neglect to distinguish between premises which are true of one set of meanings and not of the other, will fall into such mistakes as would be made by him who should conclude that blood is salt water, because both circulate in arms (of the human body and of the sea).

Admitting the scale of positive and negative numbers,

$$\dots -3, -2, -1, 0, +1, +2, +3, \dots$$

it is obvious that on the right of 0, on which we have quantities common to pure arithmetic and algebra, we pass from the greater to the less by moving our eyes from right to left; while on the left we have no meaning at all of greater and less yet established. Let us agree then that we are to pass from what we will call the greater to what we will call the less by passing from right to left in all cases; and there is no mystery in our meaning when we say that all negative quantities are less than 0, and that -10 is less than -5 .

But is this convention a purely arbitrary one? We answer that it rather bears the character of interpretation [INTERPRETATION] than of convention. Having new modes of quantity, with corresponding extensions of addition and subtraction, we are rather to ask what greater and less *ought* to mean than what, with liberty of choice, we shall make them mean. The great characteristics of greater and less (or more and less) in arithmetic are, that the more you add the more you get, and that the more you take away the less you leave, and *vice versa*. The preceding extensions of greater and less are the only ones which will allow of these theorems remaining universally true. Thus

$$3 + (-5) = -2, \text{ add more, and } 3 + (-4) = -1,$$

and -1 is greater than -2 . Again,

$$-5 - (-12) = 7, \text{ subtract less, } -5 - (-13) = 8,$$

and 8 is greater than 7.

It is however to be remembered, though no rule has been laid down upon the subject, that it may be gathered from the practice of writers that the terms *smaller* and *diminution* do not accompany *less* in its extended meaning. The former term is particularly used in the Differential Calculus to denote an approach to 0, which in a negative quantity is algebraic increase, and in a positive quantity diminution. And many, perhaps all, writers on the Differential Calculus, are lax in their use of all the comparative terms, sometimes employing them in the algebraical and sometimes only in the arithmetical sense. The inconvenience is not very great, as a student must have learned to contend with greater difficulties than those of an unexplained use of dubious terms, before he is able to make his way to the higher mathematics. But it may be useful to give him a hint that, in reading works of analysis, he would do well at first always to stop for a moment when the word greater or less occurs, and ask himself whether the problem requires and allows the extended signification or not, and to make some mark of distinction in every place. This will at once ensure the soundness of the first reading, and facilitate the second.

NOTHING, DIFFERENCES OF. This name is given to certain numbers which are used in so many different theorems that it is worth while to tabulate them, and to consider them as fundamental numbers of reference. They were first specifically noted in this point of view by the late Bishop Brinkley. We shall here confine ourselves to a description of their derivation, an expeditious mode of calculating them, a table of some of their values, and one instance of their use.

If we take a series of terms $a, b, c, e, \&c.$, and form the successive differences of a [DIFFERENCES, CALCULUS OF], the symbols $\Delta a, \Delta^2 a, \&c.$, have a meaning which refers to the excess of b above a , &c. If then a should happen to be $= 0$, the symbols $\Delta 0, \Delta^2 0, \&c.$, may stand for finite quantities: for instance in—

$$\begin{array}{r} 0 \\ 2 \\ 2 \\ 5 \\ 9 \\ 14 \end{array} \begin{array}{r} 2 \\ 3 \\ 1 \\ 4 \\ 5 \end{array} \begin{array}{r} 1 \\ 0 \\ 0 \\ 0 \\ 1 \end{array} \&c. \quad \Delta 0 = 2, \quad \Delta^2 0 = 1.$$

But as the preceding series is a set of values of $\frac{1}{2}x(x+1)-1$, in which the first term is 0 ($x=1$ gives $\frac{1}{2}1.2-1$), it would be necessary

in using several series beginning with 0, to make marks of distinction between $\Delta 0$ in one series, and that in another. The most useful case is that in which whole and positive powers of 0, 1, 2, 3, &c., form the series in question: thus if we take the series of cubes,

$$\begin{array}{rcl} 0^3 & = & 0 \\ 1^3 & = & 1 \\ 2^3 & = & 8 \\ 3^3 & = & 27 \\ 4^3 & = & 64 \\ 5^3 & = & 125 \end{array} \quad \begin{array}{rcl} 1 & 6 & 0 \\ 7 & 12 & 6 \\ 19 & 18 & 0 \\ 37 & 24 & 6 \\ 61 & & 0 \end{array} \quad \begin{array}{l} \Delta 0^3 = 1 \\ \Delta^2 0^3 = 6 \\ \Delta^3 0^3 = 6 \\ \Delta^4 0^3 = 0, \text{ \&c.} \end{array}$$

The symbol $\Delta^m 0^n$, whenever m is greater than n , stands for 0; when m is $= n$ it stands for $1 \times 2 \times 3 \times \dots \times n$. In all other cases the differences of 0^{n+1} may be found from those of 0^n by the following equation:—

$$\Delta^r 0^{n+1} = r \{ \Delta^{r-1} 0^n + \Delta^0 0^n \}$$

n	Δ	Δ^2	Δ^3	Δ^4	Δ^5	Δ^6	Δ^7	Δ^8	Δ^9	Δ^{10}	n
10	1	1022	55980	818520	5103000	16435440	29635200	30240000	16329600	..3628800	1
9	1	510	18150	186480	834120	1905120	2328480	1451520	..362880	1	2
8	1	254	5796	40824	126000	191520	141120	..40320	3	1	3
7	1	126	1806	8400	16800	15120	..5040	6	7	1	4
6	1	62	540	1560	1800	..720	10	25	15	1	5
5	1	30	150	240	..120	15	65	90	31	1	6
4	1	14	36	..24	21	140	350	301	63	1	7
3	1	6	..6	28	266	1050	1701	966	127	1	8
2	1	..2	36	62	2646	6951	7770	3025	255	1	9
1	..1	45	750	880	22827	42525	34105	9330	511	1	10
n	Δ^{10}	Δ^9	Δ^8	Δ^7	Δ^6	Δ^5	Δ^4	Δ^3	Δ^2	Δ	n

The only one not in the table is $\Delta^{(r)} 0^r$ which is always unity.

The uses of these differences mainly consist in the rapidity with which transformations can be made by means of them, whether of a simple algebraical or of a transcendental kind: such as the following, n being a whole number:—

$$x^n = x + \Delta^{(2)} 0^n \cdot x(x-1) + \Delta^{(3)} 0^n \cdot x(x-1)(x+2) + \text{\&c.}$$

$$x^2 = x + x(x-1),$$

$$x^3 = x + 3x(x-1) + x(x-1)(x-2),$$

$$x^4 = x + 7x(x-1) + 6x(x-1)(x-2) + x(x-1)(x-2)(x-3),$$

and so on. [See also OPERATION; SERIES.]

The following works contain many properties of these numbers: Herschel, 'Examples of the Calculus of Finite Differences,' *passim*; and 'Lib. Useful Knowl.: Differential and Integral Calculus,' pp. 253-261, and 307-311.

NOTICE is a term used in English law with reference to various kinds of transactions. That use of it which is most important, and which it is here proposed to explain, has reference to contracts of buying and selling, and mainly so far as such contracts come under the cognisance of courts of equity. In this sense notice signifies the knowledge of a party to the contract of any fact which is connected with the contract, and may become a matter of dispute either between the parties to the contract, or between them or any of them and any other person not a party to that contract. The term notice is most commonly applied to buying and selling of land, or some interest in land, and the matter generally in dispute is, whether the interest of a person who is not a party to the contract is in any way to be affected by it.

Notice, in English law, is an ambiguous term, and has different meanings according as we contemplate the giver or the receiver of what is called notice. To give notice is to communicate something to another person: the person who receives the communication is said to *have* notice, and when it is proved that he has had such notice, he is presumed to have knowledge of the thing communicated. Thus notice comes to have the meaning of *knowledge* when applied to him who is the receiver of the notice; and it is not always easy to avoid the ambiguity resulting from this double meaning of the word.

Notice of a fact (notice being here considered with reference to the receiver) may mean either knowledge of the fact itself, or knowledge of some other fact from which arises a legal presumption of knowledge of the fact itself. In both cases the knowledge must be proved by evidence, and the only difference in the evidence is this; in the former case a fact is to be proved, which fact, when proved, shall be considered knowledge; and in the second case a fact is to be proved, which cannot be considered as knowledge, but is a fact the establishment of which leads to a legal presumption, that is, to an inference of some fact which is considered as knowledge. If a man receive a written communication from another person of a certain demand upon him by such person, all that can be proved by evidence is that he did receive such communication; but that fact being established, all the world imputes to the receiver of such communication knowledge of the demand contained in it. The fact, in order to have any relation to the contract, must of course be such a fact as would affect the contract if it were expressly made part of it. A fact of this kind then being established, which is

It is frequently useful to have the term $\Delta^r \cdot 0^n \div 1.2.3 \dots (r-1) \cdot r$ arranged in tables. If we wish to make this separately, we have, denoting the preceding fraction by $\Delta^{(r)} \cdot 0^n$

$$\Delta^{(r)} 0^{n+1} = \Delta^{(r-1)} 0^n + r \Delta^{(r)} 0^{n-1}$$

The following table contains both the differences, and the differences divided, as just explained, up to those formed from the series of tenth powers; arranged so that simple differences must be looked for above or on the dotted lines, and divided differences below the dotted lines; the first by means of the left hand column and highest row; the second by the right hand column and lowest row. Thus—

$$\Delta^5 0^5 = 126000, \quad \frac{\Delta^5 0^5}{2.3.4.5} = 1050$$

$$\Delta^6 0^7 = 15120, \quad \frac{\Delta^6 0^7}{2.3.4.5.6} = 21$$

either knowledge or legal presumption of knowledge, the legal conclusion is, that the person who had such knowledge at the time of making the contract must be considered as having acquiesced in such fact; in other words, such fact must be considered to have the same effect as if it were expressed in and incorporated with the contract.

Notice has been divided by writers on English law into "actual" and "constructive." Of "actual notice," it is said that "to constitute a binding notice, it must be given by a person interested in the property, and in the course of the treaty for the purchase. Vague reports from persons not interested in the property, will not affect the purchaser's conscience; nor will he be bound by notice in a previous transaction which he may have forgotten. (Lord St. Leonards, 'Vendors and Purchasers,' 13th edit. p. 621.) The same author says of "constructive notice," that "in its nature it is no more than evidence of notice, the presumptions of which are so violent, that the court will not allow even of its being controverted; but courts of equity will not extend the doctrine to cases to which it has not hitherto been held applicable." The difference between the two kinds of notice seems to be rather in degree than in kind. In addition to what has been said on the general subject of knowledge, we may take an instance of what would be called actual notice in English law. We will suppose this actual notice to be a statement in writing made by a person interested in a certain piece of land and in the course of the treaty for the purchase of it, and by him handed to the purchaser. Now it is obvious that all this, when proved, does not make the knowledge of the purchaser; but these facts, when proved, are evidence, of knowledge, "the presumptions of which are so violent" that the universal consent of mankind "will not allow even of its being controverted." There is then no further distinction between actual and constructive notice, considered as a matter belonging to the general subject of evidence, than what has been already stated; and the only question which can arise in any system of law is, what facts, not capable of being considered as knowledge, shall be considered, when proved, as leading to a legal presumption of such facts as may be considered knowledge.

These general principles will be better understood by their application to particular cases, in English law, of buying and selling land. But it should be premised that there are cases of what is often called notice, in English law, where no knowledge of anything is proved, but the existence of a certain thing is proved, and then notice is legally imputed to the person to be affected by it. Thus, when there is a public act of parliament, everybody is legally supposed to have notice of it. But this is notice which arises from positive law, and is not presumed from the proved knowledge of another fact; it would therefore be more appropriate to give it some other name, and not to confound it, as some text writers do, with that which they call constructive notice. Another example of such notice made by positive law is, where there is a suit pending* which may affect the subject of sale; in this case the purchaser is also said to have notice of it, and he buys subject to what may be decreed in the suit. All conveyances by any bankrupt *bonâ fide* made and executed before the date of the filing a petition of adjudication are valid, notwithstanding any prior act of bankruptcy committed by the bankrupt, provided the person to whom

* By the Act 2 Vict. c. 11, purchasers and mortgagees are not to be bound by *lis pendens*, of which they have not express notice, unless the names, &c., of the parties to be affected thereby are registered, as the Act prescribes.

the conveyance is made had not at the time of such conveyance notice of any prior act of bankruptcy committed by the bankrupt.

Where facts are proved to be known to a man which are sufficient to make him inquire further, he is considered to know all that he might have known if he had made inquiry. For instance, if a man buys an estate which is in the possession of a tenant, notice of such possession is notice of any lease or other interest which the tenant may have in the estate; and though the seller may affect to sell the complete and immediate interest in the estate, the buyer will take it subject to the interest of the tenant. And if a tenant under a lease has some further interest in the land by agreement posterior to the date of the lease, the buyer of the land, who has notice of the tenant's possession, has constructive notice of such agreement, and therefore he buys the estate subject to all the tenant's rights. It will of course be observed that the contract of a purchaser with a seller cannot affect the previous contract, about the same land, of another person with the same seller, so far as the mutual rights and liabilities of the seller and that other person are concerned. But the question between the two persons who have dealt with the seller is, Which of the two is to have that thing which he has agreed to buy, and which of the two is to have the trouble of settling the dispute with the seller. It is determined that the subsequent contractor, who has what is called notice of the former contract, must be considered as having the benefit of his own contract, but still subject to the prior contract; and if he has bought the estate and obtained a conveyance of it, having notice of a prior contract for sale, he will be compelled to convey the estate to the person who had such prior contract with the vendor. If the prior contractor has obtained any legal estate in the land, the buyer, of course, whether he has notice or not, only obtains from the vendor such interest as he can sell.

That which is notice to a man's agent is notice to himself, provided the agent has the notice in the transaction in which he acts as agent. This doctrine is obviously founded on the legal identity of the principal and agent, in all matters which the principal transacts by his agent.

It seems to be determined that the mere fact of a man being witness to the execution of a deed, will not be notice to him of the contents of the deed; for the nature of that transaction called witnessing a deed is not in any way connected with a knowledge of the contents of the deed.

Sometimes a person who is entitled to a sum of money or the interest of a sum of money which is in the hands of a trustee, will fraudulently sell his interest twice over. A second purchaser, who has no notice of the former transaction, and gives notice, that is, communicates in a way that cannot be misunderstood the fact of his purchase to the trustee before the former purchaser does, is entitled to have what he has bought, in preference to the other purchaser. By *not having* notice, he purchases a good title, and acquires a right to what he has bought, equal to the first purchaser's right; by *giving* notice, he secures that which he has purchased. This is a good example of Notice, viewed under two different aspects, which should not be confounded.

Other examples of notice may be found in the text books.

It will be collected from what has been said, that cases of this kind of notice under consideration, are cases in which three persons at least are generally concerned, a seller, a buyer, and some person who is interested in disputing the buyer's title to the thing which he has bought. The term is also applied, though less frequently, to the case of a seller and buyer only; for that which may be called notice in the other case may be equally well called notice in this. The seller may not intend to conceal or misrepresent any fact, and he may think that he has said everything that was necessary, and the buyer may think that he was buying the whole of an estate when the vendor was only selling the estate subject to certain encumbrances; and the state of facts may be such as would be evidence of notice to the purchaser as against a party who had contracted with the vendor previous to himself. The question then comes, whether such state of facts is to be considered as notice to the purchaser, in the case now supposed, as against the vendor, and equally binding on him as it would be in the case of a prior contracting purchaser. It may be observed that the doctrine of notice, as between a seller and a single buyer, has been applied to the case of a lease, where it was held that notice of a lease to a purchaser was notice of its contents; but this doctrine was derived from a case wherein three parties were concerned, a seller, a lessee, and a purchaser, and it does not appear to have been considered that the question of notice between two purchasers, or two parties claiming an interest in land against a third person, is not quite the same thing as the case of a dispute between two persons only, a seller and a buyer. (Hall v. Smith, 14 Ve., 426, 437.) This kind of question however, in English law, would be more properly considered under the heads of Concealment, Suppression, or Misrepresentation, which are a species of fraud; or under the head of Mistake.

The question of notice is one of great practical importance. So far as relates to what shall be evidence of notice, it will vary greatly in different systems of jurisprudence; so far as concerns its true nature, it belongs to the general doctrine of contracts.

NOUN (in Grammar), the name of one of the parts of speech into which grammarians have distributed the words of a language. The noun generally expresses the subject of discourse, or the name (*nomen*)

of the thing spoken of, as *horse*, *table*, *darkness*, &c.; but it may also be used as the predicate, as in the sentence, "Tin is a metal," where both "tin" and "metal" are nouns.

So far as respects the form of nouns, that is, the sounds of which they are composed, they are capable of classification in all languages. The nature of this classification may be explained from examples in our own language. Many nouns are simple roots, as *horse*, *ship*, *man*, *tree*; while others are formed by adding a suffix to the root or to other words. [NOTION, NOTIONAL.]

The following list of nouns, formed by suffixes, belong to the Saxon part of our language. A few examples of each suffix are given in order to show the use of each suffix more clearly:—

Er.	Ster.	Ard.	Eer.
build-er	game-ster	drunk-ard	mountain-eer
box-er	malt-ster	slugg-ard	chariot-eer
walk-er	song-ster	dast-ard	musket-eer
scoff-er	pun-ster	blink-ard	engin-eer

Some of the words in *er*, *ster*, and other terminations, have a corresponding feminine termination in *ess*, *ix*, or *stress*, as *murderess*, *songstress*, *executrix*. The termination *ix* is of Latin origin.

Ling.	Kin.	Let.
fat-ling	lamb-kin	rivu-let
first-ling	pump-kin	cut-let
dar-ling (dear-ling)	pip-kin	stream-let
fond-ling	manni-kin	is-let

These three terminations generally, but not always, give to the root the notion of smallness, and hence they belong to the class called diminutives.

Dom.	Hood.	Ness.
king-dom	boy-hood	bad-ness
wis-dom	child-hood	base-ness
prince-dom	false-hood	cold-ness
thral-dom	man-hood	dark-ness

Rick—as bishop-ric; Wick—as bail-wick.

Ship.	Th (from adjectives, with a change in the vowel).	T (mostly past participles).
friend-ship	leng-th	gift
hard-ship	bread-th	draft
partner-ship	dep-th	joint
court-ship	streng-th	theft

The following terminations are of Latin and Greek origin, though most of them seem to have come through the Norman portion of our language:—

Acy.*	Age.†	An or Ian.	Anc.	Ancy.‡
conspir-acy	append-age	pag-an	abund-ance	depend-ancy
fall-acy	band-age	artis-an	repent-ance	expect-ancy
suprem-acy	broker-age	guard-ian	resist-ance	occup-ancy
lun-acy	cord-age	traged-ian	observ-ance	vac-ancy

Ary.	Ate.	Ence.	Ency.
api-ary	advo-cate	consci-ence	ag-ency
lumin-ary	potent-ate	consequ-ence	clem-ency
emiss-ary	prim-ate	impot-ence	curr-ency
libr-ary	gradu-ate	infer-ence	tend-ency

Ent.	Ice.	ics.	Ion.
correspond-ent	mal-ice	eth-ics	adopt-ion
presid-ent	just-ice	opt-ics	animat-ion
stud-ent	avar-ice	mechan-ics	anticipat-ion
ag-ent	coward-ice	phys-ics	corrupt-ion

Ism.	Ist.	Ment.	Ory.
athe-ism	bapt-ist	allure-ment	audit-ory
bapt-ism	de-ist	enjoy-ment	vict-ory
critic-ism	flor-ist	entice-ment	direct-ory
fanatic-ism	fatal-ist	frag-ment	deposit-ory

Or or Tor	Tude.	Ty.	Ure.
correct-or	alti-tude	facili-ty	depart-ure
inspect-or	forti-tude	liber-ty	fig-ure
jur-or	grati-tude	plen-ty	literat-ure
edit-or	lati-tude	civili-ty	press-ure

The preceding list contains the majority of the terminations of nouns in the English language which are not simple roots. The number, case, and gender of nouns in general are explained in the articles DUAL NUMBER, GENDER, ABLATIVE, and ACCUSATIVE CASES.

* Usually formed from adjectives in *ate*, as *accur-ate*, *accur-acy*.

† Apparently from the barbarous Latin *agium*.

‡ Usually formed from adjectives in *ant*, as *abund-ant*, *abund-ancy*.

NOVATIANS, a Christian sect which arose in the middle of the 3rd century. Their leader, Novatianus (or as Lardner prefers to call him, following the Greek writers, Novatus), was a presbyter at Rome, who, after the death of Fabian, bishop of Rome (A.D. 250), and the election of Cornelius as his successor (A.D. 251), refused to submit to the authority of Cornelius, and procured from three bishops his own ordination as bishop of Rome. Upon this, Cornelius called a council at Rome, and excommunicated Novatian and his adherents, who immediately formed a distinct sect, and thus became schismatics. But Novatian is also reckoned as a heretic, on account of his opinions respecting those Christians who after baptism had fallen into open sin, whom he declared that the Church had not the power to admit again to her communion, even though they should give satisfactory evidence of their repentance. In consequence of this strictness of discipline, his followers obtained from the Greek writers the name of *Cáthari* (*καθαροί*), that is, Puritans. In other points the opinions of Novatian did not differ from those of the Catholics. Some writers charge him with unsound opinions respecting the Trinity, but there is ample evidence to disprove this accusation. His later followers condemned second marriages. Novatian is highly spoken of by the ecclesiastical writers for his learning, eloquence, piety, and exemplary conduct. It is true that Cornelius accuses him of very disreputable conduct in the means by which he obtained ordination, and in other matters; but these are the statements of a violent opponent, couched in very unmeasured language, and some of them are highly improbable.

Novatian was assisted in his proceedings by Novatus, a presbyter of Carthage, whom Cyprian calls the author of the schism; and he numbered also among his followers some bishops and several presbyters. His sect spread widely, and embraced at various times some men of very high character and attainments. The Novatians were included in the severe edict which Constantine issued, about A.D. 331, against the Valentianites, Marcionites, Cataphrygians, and other heretics; but it is thought that, through the influence which some of their leaders had with the emperor, they suffered little on that occasion. Under the Arian emperors they shared in common with the orthodox in the persecutions which they endured; but under the Catholic emperors they appear to have enjoyed repose on account of their orthodox opinions on the Trinity. This sect declined in importance during the 5th century.

Novatian wrote several works, of which there remain a treatise, 'Of Jewish Meats'; another, 'Of the Trinity,' or 'Of the Rule of Faith,' a letter of the Roman clergy to Cyprian, written during the vacancy of the see of Rome, after the death of Fabian, in August, 250. There is another letter to Cyprian, written in the same year, but it is not certain that Novatian was its author. Jerome gives a catalogue of Novatian's works, among which are two, 'Of Easter,' and 'Of Circumcision.' The Novatians asserted that their leader suffered martyrdom, but of this we have no proof.

(Eusebius, *Hist. Ecc.* vi. 43; Hieronymus, *De Vir. Illust.* chap. 70; Epiphanius, *De Hæresiis*; Lardner's *Credibility*, pt. ii. chap. 47; Mosheim's *Ecclesiastical History*, cent. iii. part ii.; Neander's *Kirchen-geschichte*.)

NOVEL. It will be as well to draw a distinction at starting between romances and novels; the one term includes all fictitious narratives of the kind called romantic, whether in prose or verse; the other is used to designate that species of romance which is most common at present. Those who are accustomed to look upon all literary composition as depending for its changes on that prevalent tone and character of society, which are usually known by the name of the spirit of the age, will easily allow that imaginative writings are not excepted from the general rule; that they are in fact the expression of the age in which they appear. It remains then for us to find out, if possible, what relation they bear to that prevalent tone of society to which we have already alluded, as the spirit of the age.

A comparison between the novel and other imaginative compositions, such as narrative, lyrical, or dramatic poetry, will show that while the latter depend for their effect on our tastes and sympathies as men, the former requires us to be interested in the circumstances of the plot as well as in the characters themselves. The interest excited by the 'Iliad,' and by 'Hamlet,' exists independently of our knowledge of the history of Troy or of Denmark; and hence the universal celebrity of those poems. They have been read and will be read with delight, not only by one age or country, but by all. They exhibit pictures of *humanity*; and, as such, do not depend for their popularity on the fact of their readers being interested by the customs which they describe or the scenes in which the stories are laid. It is as a man, not as a prince of Denmark, that we are interested in Hamlet. If Hector and Andromache had been natives of the South Sea Islands, we should have read the description of their parting with as much sympathy as we do now.

In novels, on the contrary, we require, in order to be fully satisfied, to be interested in the circumstances, the dress, manners and language of the characters, as well as in the characters themselves. But these circumstances, the outward dress of the story, are precisely those parts in which the peculiarities of age and country are developed—those which render the hero of the novel an individual, not the representative of a class. If we acknowledge thus far, we shall see that the interest which the novel excites depends on more causes than that of the

narrative or dramatic poem. But being a more intense, it is also a more confined, interest; and thus we see why the ponderous romances of the 17th century have ceased to delight the world, while the 'Iliad' is as fresh to us as it was to Plato or Cicero.

This additional source of interest however is that which depends in itself on the peculiarities of the age in which any one novel or class of novels appears. Thus the stilted romance of Elizabeth's time was the legitimate offspring of a taste then very prevalent for an ideal state of pastoral life called Arcadian. The readers in that day were the higher ranks, the court and the nobility, and the novel both led and followed their taste. In another country we find romances of chivalry particularly current when the age of chivalry was nearly passed, and when the realities of Moorish warfare had been succeeded by a fashionable enthusiasm unaccompanied by action. Such were the novels which Cervantes began by caricaturing and ended by surpassing.

Sir Walter Scott's novels are in like manner the legitimate creation of their age. Percy's 'Reliques' and some other books had given a retrospective turn to literature. Men began to find that Pope and Dryden, or even Milton, did not contain all that was worth knowing in the literature of England. A race of antiquaries sprang up, and with them an antiquarian novelist. Goethe's famous saying about Shakspeare, which Carlyle has so cleverly applied to Scott,—"that Shakspeare formed his characters from within outwards, Scott from without inwards," is so true, that any one who bears it in mind while reading Scott will not fail to see that the attraction of the 'Waverley novels' depends more on the dresses and decorations than on the actors.

To quote one more instance; during the first half of the last century the great object of attention was "the town," by which was meant the profligate life spent by men of fashion. A glance at the poetry of that age is enough to show that Nature had small charms for the reading public, and that fashion was then everything. If we turn to the novelists, to Richardson, Fielding, and Smollett, and then to their descriptions, can anything be more obvious, than that the external dress of the novel—that by which it is distinguished from other narrative works of imagination,—depends entirely on the age in which it is written, and is in effect a tolerably faithful but somewhat exaggerated reflection of the favourite ideal objects and pursuits of the reading classes at the time.

But there is another salient feature in the novel, which it possesses in common with the poetical romance, and which distinguishes it most completely from all classical fictions. We refer to the important part played in almost all novels by that kind of love which goes by the name of romantic.

It cannot be doubted that the influence of Christianity and of the old German spirit upon the nations of modern Europe has contributed to alter the treatment and condition of women, not only in degree but in kind. To the eye of a Roman observer, one of the most remarkable peculiarities of the German nation was the veneration paid to women, and this veneration, transmitted through generations, affected in no unfavourable degree by Christian precepts, although changing in appearance with the change of ages, still exists in that gallantry of which the Romans and Greeks seem to have been wholly ignorant, and which in the romantic novel, as being a picture of human life, plays a most important part. But it is still to be remembered that it is not the passion of love as a classical author would have described it, but the passion as developed in those nations among whom romantic tales have been principally current, which thus predominates in the romantic novel.

The popularity of novels is one of the most curious features of our literature; and it is to be observed that it is attended with an almost entire discouragement of dramatic composition, and with a marked preference on the part of those who apparently patronise the drama, for scenic effect, in place of accurate dramatic delineation of character. There is scarcely one tragedy worth mention of a date posterior to the time of Fielding. 'Philip van Artevelde,' the offspring of our day, and, although far below it in merit, Talfourd's 'Ion,' are worth notice, as well for other reasons as because they have been accompanied by an effort, in act, to redeem the stage from serving as the mere vehicle of dramatised novels. But we cannot give to 'Philip van Artevelde' the name of a drama; indeed the author himself styles it a dramatic romance; and its length and the character of many of its incidents bring it rather under the romance than the drama. We have drawn a distinction between the romance and the novel, the former being the more comprehensive word; but we must still bear in mind that a prose novel stands in the same relation to a later age that a poetical romance does to an earlier, for poetry constitutes the only possible literature of an age of reciters; and it is not until men begin to read for themselves that prose comes into being.

There is another feature about the novels of the present day which deserves especial notice, and that is the manifold forms which they assume. We have them as naval tales, military records, love stories, political memoirs, the diaries of clergymen, lawyers, and physicians, novels embodying theological disquisitions,—suited in short to every class of readers. From this we see how much the demand influences the supply, even in that most incorporeal of all manufactures, book-making. That the appetite is fed by the supply is also true, but not to an extent sufficient to justify us in supposing that the one depends

entirely upon the other. The manifold character of modern romantic literature, as compared with that uniformity which distinguished the romances of the middle ages, when author after author exhausted his powers in adding to one bulky record of the fall of Troy, or the conquests of Alexander, is the last proof which we need bring to show that romances do really depend upon and go along with the prevailing tone of the age in which they appear.

It is not the province of this work to enlarge on the probable or actual effects of any course of reading, but it may be as well to point out that the injury supposed to be done to the mind by novel reading is not peculiar to any one kind of study. A constant devotion to any abstract speculation notoriously deadens the taste; and too much cultivation of any one pursuit necessarily gives the corresponding part of the mind a growth disproportionate to that of the rest. The peculiar evil of novel-reading depends on the bad quality of the food devoured, which pampers our love for ideal griefs and joys, to the prejudice of all well-organised efforts to grapple with the realities of life.

NOVELLÆ. [JUSTINIAN'S LEGISLATION.]

NOVEMBER, the eleventh month of the Julian year, was the ninth in the year of Romulus, whence it received its name. This name was assigned to it in the Alban calendar. It originally consisted of thirty days, which were continued by Romulus and Numa. Julius Caesar gave it another day, but Augustus reduced it again to thirty, and this number it has ever since retained.

Our Saxon ancestors called November *Blot-monath* (blood-month), the month of sacrifice, because at this season the heathen Saxons made a provision for winter, and offered in sacrifice many of the animals which were then killed. This is distinctly stated in an ancient account of the Saxon months, printed in Hicke's 'Thesaurus' (vol. i., p. 219). It was common at this season to slaughter oxen, sheep, hogs, &c., for the use of the ensuing winter. The stock of salted meat prepared at this time was to last through the winter months till vegetation came again sufficiently forward to enable them to resume the use of fresh provisions. Some notion of the vast extent to which the opulent provided for themselves and their retainers at this season may be formed from the contents of the larder of the elder Spenser, in 1327, which, in the month of May, contained "the carcasses of eighty salted beeves, five hundred bacons, and six hundred muttons," the reliques of his winter provisions.

Martlemass or Martinmas beef, cured about the festival of St. Martin, the 11th of this month, was a provision formerly well and in some places still known. The Spanish proverb, "His Martinmas is coming, when we shall be all hogs alike," alludes to the slaughter of swine at this period.

(Pitisci, *Lexicon Antiq. Roman.*; Bosworth's *Anglo-Saxon Dict.*; Brady's *Clavis Calendaria*.)

NOVICE, the appellation given to persons of either sex who are living in a monastery, in a state of probation previous to becoming professed members of a monastic order. Persons who apply to enter the noviciate state, on being admitted by the superior of the monastery, promise obedience during the time of their stay, and are bound to conform to the discipline of the house, but they make no permanent vows, and may leave, if they find that the monastic life does not suit them. The period of the noviciate must not be less than one year, and the person who enters as a novice must have attained the age of puberty. Richard, in the 'Bibliothèque Sacrée,' article 'Novice,' describes the qualities required according to the canons of the Council of Trent for the admission of a novice: they are health, morality, voluntary disposition for a monastic life, intellectual capacity, &c. No married person can be admitted unless by the consent of both parties; no person who is incumbered with debts, or whose assistance is necessary for the support of his parents, is admissible. Widowers and widows may be admitted as novices, unless their labour is required for the support of their children. After the termination of the year of probation, the novice, if he (or she) persists in his vocation, and his conduct and capacity have proved satisfactory, may be admitted into the order by taking the solemn vows which are binding for life. Ducange, in his 'Glossarium,' article 'Novitius,' quotes the 34th canon of the Council of Aquisgrana, A.D. 817, in which superiors of monasteries are cautioned against admitting novices with too great facility, and without a full examination of their disposition, morals, and mental and bodily qualifications. But in after-ages, as the number of monasteries was multiplied beyond measure, prudential restrictions were disregarded, and every means were resorted to in order to induce young people to enter the monastic profession, and parents often forced their children into it against their will. The misery and guilt which resulted from this practice are well known, but few perhaps have exhibited them in so vivid and fearful a light as the Italian writer, Manzoni, in his 'Promessi Sposi,' in the episode of 'Gertrude.' It was in order to guard against such abuses and their fatal results that the Council of Trent, session 25, can. 17, prescribed that female novices, after the expiration of their noviciate, should leave the walls of the monastery and return to their friends, and be carefully examined by the bishop of the diocese, or by his vicar by him delegated, in order to ascertain that they were under no constraint or deception, that they were fully aware of the duties and privations of the monastic life, and that they voluntarily chose to enter it. These humane precautions,

however, have been evaded in many instances; and it may be doubted whether a very young person should be allowed to bind himself for life by irrevocable vows.

NUCLEUS (a small nut), a term first given to the central and condensed portion of a comet, and thence to the central part of any appearance which is transparent towards the extremities and opaque towards the centre.

NUISANCE, or NUSANCE, is a term in English law derived immediately from the French *nuire*, and ultimately from the Latin *nocere*, "to hurt;" signifying an unlawful act or omission which occasions annoyance, damage, or inconvenience to others. Nuisances may consist of injurious acts done, or of omissions to perform duties prescribed by law, and are of two kinds, *common* or *public* nuisances, which affect all the queen's subjects, and *private* nuisances, which injure individuals. Instances of the former are, annoyances in highways, public bridges, or navigable rivers, which are produced by rendering the passage inconvenient or dangerous, either positively by actual destructions, or negatively by omitting to repair in cases where the law imposes the duty of repairing.

Noxious processes of trade or manufacture in towns are common nuisances by reason of the danger to the health of the inhabitants; and brothels, disorderly alehouses, gaming-houses, and unlicensed stage-plays are held to be common nuisances, both on account of the injury done by them to public morals and of the danger to the public peace by drawing together numbers of dissolute and irregular persons. The remedy for a public nuisance is by presentment or indictment; and the offender, upon conviction, may be punished by fine and imprisonment. It is said also that in the case of a positive obstruction to the free enjoyment of a public right, it may form part of the judgment that the offender shall remove the nuisance at his own cost; "and it seemeth to be reasonable," says Hawkins (book i. ch. 75, sect. 15), "that those who are convicted of any other common nuisance should also have the like judgment."

Private nuisances are annoyances which affect individuals only. Thus, if my neighbour builds a house so near to mine that he obstructs my ancient lights, or throws the water from his roof upon my house or land, this is a private nuisance; so also if he keeps noisome animals, or sets up an offensive trade or hazardous manufactory so near to my dwelling-house that the free enjoyment of my property is interrupted either by injury to my health or comfort, or the apprehension of danger. The remedy for a private nuisance is by action, in which damages may be recovered according to the injury sustained. Private nuisances, injurious to health, may be summarily suppressed on application to the magistrates, under the Nuisances Removal and Diseases Prevention Acts.

NULLITY OF MARRIAGE. [MARRIAGE.]

NUMBER. The general considerations which this word would suggest cannot be treated independently of those required in treating the notion of ratio in general. As this will form a part of the subject of PROPORTION, we refer to that article as the continuation of the present one.

The notion of number is suggested by repetition or succession; and it is customary to call the actual things repeated, considered as a collection, a concrete number; while the notion formed from comparing the collection with one of the things collected is called an *abstract* number. This abstract number arises from repetition of objects, in which the attention is directed to the repetitions as repetitions, and not to the objects as distinguished from any other objects. It is therefore a number of times, not a number of things. [MULTIPLICATION.]

If we never numbered any things capable of division into parts like themselves, our notion of number would rest in what is now called *whole* number. If the intellect were taught to count by the beating of a clock, and never came in contact with any other magnitude except that of the intervals between the beats, it is difficult to see how the idea of fractions would be obtained. But when we come to put together continuous magnitudes, which might increase or decrease without any alteration except that of magnitude, such as lines, surfaces, &c., we then begin to see that the unit is purely arbitrary, considered as a magnitude, so that the consideration of smaller or larger units, and the reduction of processes from one unit to another, become necessary. Hence the doctrine of fractions, and finally that of INCOMMENSURABLES.

The unit of magnitude and the unit of repetition are as distinct as concrete and abstract number. A given magnitude being chosen, we may fix our own ideas of other magnitudes and convey them to other persons by describing the repetitions of the given unit which will severally give the other magnitudes: but it is incorrect to say that in arithmetic we can perform all operations upon magnitudes represented by numbers; the operations are performed by our minds upon notions of repetition, not of magnitude. Any question of numbers arising out of geometry might, so far as the pure arithmetical processes are concerned, as well have the prototypes of its numbers in collections of beats of a clock or motions of the arm, as in repetitions of lengths or areas. It is not true that such simple successions would suggest as many problems as geometry or commercial business; but that is a distinct consideration.

Discussion formerly took place upon the question whether 1 repre-

sents a number; it being asserted that *number* must be *more than one*. The settlement of such a question depends upon convention entirely, and is very easy. In the common sense of the word neither 1 nor 2 are numbers: a number of men, or of pebbles, would suggest the idea of more than two; in fact the colloquial word *number* means indefinitely many; more than the eye can decide on without counting; *several*, that is to say, as many as require the *severing* which takes place in counting. With different persons this commencement of number, vulgarly speaking, may be different; all persons discern *three* without counting, and probably *four*; but it is certain that *five* must be severed by most persons, and *six* probably by all. Those who watch the progress of children can easily see that their scales of reckoning are successively one and more; one two, and more; one, two, three, and more.

In the common playing-cards we decide by forms, not by numbers; and were not the nine distinguished from the seven by the different positions of the odd spot, there would be continual mistakes.

In mathematical language, every numerical symbol is called number, including 0, 1, fractions, whole numbers, and even *infinity*.

The talent of easily combining and remembering numbers, or of calculation, is a perfectly distinct thing from that of mathematical invention, reasoning, or application; though the two are frequently confounded. Taking mathematicians of the highest order, some have been singularly gifted in this respect, some distinguished in neither way, and some more than commonly deficient.

A very deceptive mode of speaking is common with regard to numbers, which divides them into *cardinal* and *ordinal*. Thus *one, two, three, &c.*, are cardinal numbers, while *first, second, third, &c.*, are ordinal. The real distinction is that of numeral *nouns* and numeral *pronouns*, to the latter of which the term ordinal might properly be applied. That *first, second, third, &c.*, are really pronouns is obvious if we consider that, so far as they go, *this, that, and the other* would supply their places. The so-called cardinal numbers denote collections; the ordinal numbers point out only the places of the several units of which a collection is composed. Even *one*, when its force is simply selective or distinctive, is a pronoun, as in "one or another."

[ARITHMETIC; MAGNITUDE; PROPORTION; QUANTITY; UNIT.]

NUMBERING MACHINES differ from the apparatus described under MACHINES, CALCULATING, in being less complicated, and (for the most part) in performing operations of a less comprehensive character. Their work is that of numbering, or enumerating, and registering the results in some conspicuous way, with or without printing.

In the article MINT, a description is given of Colonel Harness's machine for weighing the blank pieces of gold which are to be stamped into sovereigns and half-sovereigns; and mention is made of another machine, invented by Mr. Cotton, employed at the Bank of England. As an example of one of those machines which calculate, or rather enumerate, by means of weighing, a few words of description may be given here. It is computed that 30,000 sovereigns pass over the Bank counter every day; and as it is necessary to ascertain whether these are of due weight, Mr. Cotton, when Governor of the Bank, in 1843, invented a machine to lessen the anxious labours of the bullion weighers, and caused it to be constructed by Mr. Napier. A pile of gold coins is placed in a small hopper at the top of the apparatus, and passes down a tube. A system of clockwork within the machine then seizes the lowest coin of the pile, and places it on a little platform, shaped like a quadrant, suspended over one end of a balanced beam. If the coin is of standard weight, a small tongue or slider advances and pushes it into one division of a till or box; if light, another tongue pushes it into a second division of the same till. No account is taken of those coins which are heavier than the standard; for such specimens are extremely rare. The tongues act at right angles to each other. While one coin is being thus weighed, a succeeding one is on its way from the hopper to the platform, and the moment the preceding coin is disposed of, another supplies its place. Each machine can weigh 10,000 sovereigns in six hours, separating all which are lower than the standard by a quantity so small as a fraction of a grain.

These machines, as well as Baron Leguier's for separating coins into three groups, according as they are true, light, or heavy; and Captain Smith's, for testing rupees at the Calcutta mint—perform their working by *weighing*. There is, however, a coin-counting machine employed at the California mint. The coins are thrown in sufficient quantity on a peculiar kind of tray, and shaken; they fall into oblong grooves, and all superfluous coins slide off when the tray is held sloping. In a very few seconds, one layer of coins covers the whole surface of the tray; and then the number is known to be 1000, neither more nor less.

Very ingenious machines are now made for combining numbering and dating with printing. Among many other kinds, the remarkable machine for numbering railway tickets was invented by the late Mr. Thomas Edmondson, while a station-clerk on the Newcastle and

Carlisle railway. To facilitate the interchange of traffic between different companies, it is necessary that each passenger's ticket should be numbered, and Edmondson's machine is so contrived as to print the consecutive numbers of a whole series by a process nearly automatic. The colour of the cardboard is selected by the respective companies; and the general particulars, as to stations, class of train, and number of ticket, are printed at the establishment of the manufacturers; but the day of the month is printed in a few seconds, by a small machine in front of the booking-clerk. In the general printing, so done that one person can print 300 per minute, a pile of blank tickets is placed inside a receptacle, which also contains a little form of type relating to the names of the stations and the class of carriage. A ribbon saturated with ink, travelling over a wheel, is brought in contact with the type, which is instantly pressed down upon one of the blank tickets; the tickets are withdrawn one by one by a feeder from the bottom of the pile, and placed just in the proper spot for the inked type to act upon it. Every ticket receives a number, varying from 0 to 10,000. Raised numbers are engraved on the peripheries of two brass wheels, which revolve at different velocities; different numbers are presented for inking after each printing, in such a way that a series of tickets receive their numbers in proper order. It is not possible for the machine to print these numbers erroneously, so long as it remains in working order. The small upright apparatus on the booking-clerk's counter at a railway-station is the *dating-press*. It contains wheels, types, ink, and an inking ribbon; the clerk inserts one end of each ticket a little way between two cylinders, and draws it smartly away again instantly, with the date printed on it; all he has to do else is to change the date-types once a day, and to see occasionally that the ribbon is properly saturated.

Baranowsky's ticket printing, numbering, and registering machine; Lewthwaite's machine for numbering railway or pawnbrokers' tickets, or paging books, or printing any consecutive series of numbers; the machines invented by Church and Goddard, and by Messrs. Harild, for printing and numbering railway tickets; and those invented by Mr. Shaw and Mr. Schlosinger, for paging ledgers and cheque-books—are all examples bearing a similarity to Edmondson's sufficiently close to render separate description unnecessary.

A remarkable process of printing a series of consecutive numbers is described under BANK-NOTE MANUFACTURE.

There is a great variety of instruments in which number or quantity is indicated by a dial, instead of by printing. Mr. Whiffen's apparatus records the number of times that a certain operation is performed; it was intended primarily to be applied to the trap-door of a ship's coal-weighing machine, to register the number of times that the door of the shoot has been opened for the discharge of coals; but a slight modification will enable it to register the filling of measures of grain, or the number of times that a porter or carrier has crossed a platform with goods; it comprises toothed-wheels, ratchets, and ratchet-wheels, a dial-plate, and index hands. Walker's *operameter* registers the amount of work done by certain machines. There is a shaft which may be connected with any one of such machines; the shaft rotates as fast as the machine, and gives motion to a train of wheelwork, with a dial-face and index hands; the hands thus become a measure and register of the amount of work done by the machine, so far as that work is denoted by revolutions of machinery. Something similar to this is the apparatus called a *counter*, often used in cotton factories to count or record the revolutions of particular parts of a machine. Scientific men now make large use of contrivances which measure and register certain phenomena with which they are concerned, such as heat, moisture, barometrical pressure, rain, wind, and tides—either by an index-hand moving round a dial, or by a pencil marking on a revolving cylinder of paper. Registers of time, space, and speed, are numerous and varied. All kinds of horological instruments belong, of course, to the first of these three groups. The *odometer* measures the length of roads and streets, and records the results on a dial suitably graduated. The *pedometer* counts and registers the number of steps taken by a person in walking, thereby measuring the distance walked if the steps are equal in length. Whishaw's *velocimeter* is intended to measure the velocity of a railway train, by showing how far an index-hand has moved during the passage of the train from one mile-post to another. Redier's *horographe* is intended to register the rate of speed between two stations, and the exact time at which the train arrives at each. Carey's measuring machine is a contrivance for recording the number of revolutions made by the wheel of a carriage, as denoted by the slow movement of an index-hand. The *turnstiles* at the pay places of bridges and exhibitions show, by an index-hand, the number of times that the stile has been turned to permit a passenger to pass through. Arèra's *pendule indicateur*, and many forms of *tell-tale*, are contrivances which test and register the vigilance of watchmen, guards, police, night porters, &c.: in most such machines, the man is expected to touch a particular part of the apparatus at certain intervals during the night; and if he fail to do this, a dial-face or other register tells a tale of his negligence, and of the period of the night when the negligence occurred. Numerous *indicators*, *monitors*, and *detectors*, have been proposed for use in omnibuses and cabs, either to measure the distance run, or to register the number of persons who have entered; in some of these, the passenger, when he enters or leaves the vehicle, steps on one end of a lever or spring, which works an index-hand; in others,

the seat on which he sits has some such lever or spring beneath it; none of these machines, however, has come regularly into use.

A machine called the *timbre additionneur* combines the principles of both groups just described: namely, those which print consecutive numbers on tickets and pages, and those which register quantities on dial-faces. There are stamping dies, levers, inking-tables, wheel-work, and index-hands. With the full apparatus, the machine can number and stamp such documents as bills, letters, and share-certificates, and can record on the dial the number of stampings thus effected; while, with the stamping and inking apparatus removed, it may be made to count the passengers through a turnstile, or the revolutions of a coach-wheel, or the length of yarn spun by a machine, or that of cloth woven, or the revolutions of a fly-wheel or water-wheel.

NUMBERS, APPELLATIONS OF. Various names have been given to classes of numbers, each expressive of properties common to all in its class: they are pointed out in the following list:—

The whole scale, 1, 2, 3, &c., is called that of *natural* numbers; it is subdivided into the scale of *odd* numbers, 1, 3, 5, &c., and *even* numbers, 2, 4, 6, &c. These again are subdivided into *oddly odd* numbers, 3, 7, 11, &c.; *evenly odd* numbers, 1, 5, 9, &c.; *oddly even* numbers, 2, 6, 10, &c.; and *evenly even* numbers, 4, 8, 12, &c. These latter appellations are not in universal use, though they are very convenient. Thus with reference to division by two and by four, all numbers have names; but not with reference to any higher numbers. The expression of a number which divided by m leaves a remainder n (namely, $mx+n$, where x is a whole number) is so simple, that it is more easily written than described. When 0 is included in the list, it is considered as divisible without remainder by every number.

The division of numbers into *square* numbers, 1, 4, 9, 16, &c.; *cube* numbers, 1, 8, 27, 64, &c.; *fourth powers*, 1, 16, 81, 256, &c., and so on, may be carried to any extent.

A *prime* number is any one of the list 1, 2, 3, 5, 7, 11, 13, &c., no one of which is divisible by any number except unity and itself. A *composite* number is any one which is not prime.

A *figurate* number is any one out of the following series, the first excepted, which is only introduced as a basis.

	1	2	3	4	5	6 &c.
I.	1	3	6	10	15	21 &c.
II.	1	4	10	20	35	56 &c.
III.	1	5	15	35	70	126 &c.
IV.	1	6	21	56	126	252 &c.
V.	1	7	28	84	210	462 &c.
&c.				&c.		&c.

Each number is the sum of the numbers in the preceding row: thus 84 is the sum of 1, 6, 21, and 56, and 84 is the fourth number of the fifth order of figurate numbers. The n th number in the first

order is $n \frac{n+1}{2}$, in the second order $n \frac{n+1}{2} \frac{n+2}{3}$ in the third order $n \frac{n+1}{2} \frac{n+2}{3} \frac{n+3}{4}$ and so on.

Polygonal numbers, as their name imports [POLYGON], may be subdivided into triangular, quadrangular, pentagonal, hexagonal, &c. To find the numbers which bear the name of an n -sided figure, form a series beginning with 1 and consisting of terms increasing in arithmetical progression, with a common difference $n-2$: and form the sums of terms of these series in the manner described. Thus for decagonal numbers, we have—

	1	9	17	25	33	41 &c.
1	1	10	27	52	85	126 &c.

and the decagonal numbers are 1, 10, 27, &c. The m th number of the n -sided order of figures is

$$1 + nm \frac{m-1}{2} - (m-1)^2$$

The following are some of the polygonal numbers:—

	1	3	6	10	15	21 &c.
Triangular	1	3	6	10	15	21 &c.
Quadrangular	1	4	9	16	25	36 &c.
Pentagonal	1	5	12	22	35	51 &c.
Hexagonal	1	6	15	28	45	66 &c.

Pyramidal numbers are formed by summing the polygonal numbers; thus, to find pentagonally pyramidal numbers, take the pentagonal numbers—

	1	5	12	22	35	51 &c.
1	1	6	18	40	75	126 &c.

Numbers were once considered as *abundant*, *perfect*, and *defective*. An *abundant* number was one in which the sum of all its divisors (unity included, but not itself) exceeds the number: thus 12 is an abundant number, because $1+2+3+4+6$ is greater than 12. A *perfect* number was one in which the sum of all the divisors was equal to the number: thus 6 is $1+2+3$, and is a perfect number, as is 28, or $1+2+4+7+14$. A *defective* number was one in which the sum of the divisors is less than the number, as 10, in which $1+2+5$ is less than 10. Whenever $2^n - 1$ is a prime number, then $2^{n-1}(2^n - 1)$ is

a perfect number; thus $2^7 - 1$, or 127, is a prime number, whence $2^7(2^7 - 1)$, or 64×127 , or 8128, is a perfect number.

Amicable numbers are those each of which is equal to the sum of all the divisors of the other. Such are

284 and 220
17296 and 18416
9363583 and 9437056

Other names have been invented descriptive of classes of numbers; but the preceding are those which most often occur in the past history of mathematics. With the exception of *SQUARE*, *CUBE*, *PRIME*, *even*, and *odd*, the preceding appellatives rarely appear in modern works.

NUMBERS, OLD APPELLATIONS OF. The student of books verging on the middle ages will occasionally meet with some designations of numbers, or rather of the ratios of numbers to numbers, which may need explanation in a work of reference. Corresponding terms are found in the Greek writers, particularly in those on music, and they seem to have obtained universal currency in the middle ages by means of the work of Boethius on Arithmetic, which was a general object of study up to the middle of the 16th century.

These words illustrate a fault which has been avoided in our day by the adoption of the opposite extreme. The ancients often overloaded a subject with terms; the moderns cannot prepare them as fast as they want them. The higher analysis now abounds with objects of thought for which there are no names except complex algebraical symbols; the old arithmeticians strove to find names for all the varieties of numerical ratio.

In describing these words, we shall, where we can, use the English form of the Latin adjectives, to avoid overloading our article with Latin words: the adjectives accompany the word *numerus*, not *ratio*. The ratio of the greater integer number to the less was one of the following five, multiple, superpartient, superparticular, multiple superparticular, or multiple superpartient. The ratio of the less to the greater was either submultiple, subsuperparticular, subsuperpartient, multiple subsuperparticular, or multiple subsuperpartient.

The term multiple has been preserved, and its species, duple (double), triple, quadruple, quintuple, &c. Thus 10 to 2 is a multiple ratio, namely quintuple: that of 2 to 10 is submultiple, namely subquintuple. Superparticular ratio (part, that is, aliquot part, over) is when the greater contains the less and a submultiple of the less: its varieties are sescuple or sesquialter, sesquitercius, sesquiquartus, &c. Thus the following ratios are superparticular: 15 to 10, which is sesquialter; 16 to 12, which is sesquitercius; 15 to 12, sesquiquartus; and so on. But the ratio of 12 to 15 is subsuperparticular, namely subsesquiquartus. One of these names is still preserved in our language, in the *sesquialter* stop of an organ. The ratio of 3 to 2 (a sesquialter ratio) is that of the length of a pipe to the length of a pipe which sounds the fifth above the note of the first. Accordingly when a stop was made to sound with the ordinary stop, but a fifth above it, the name sesquialter was given to the stop which gave the higher note.

Superpartient ratio, according to Boethius, is that in which the major term is twice the minor all but an aliquot part. Its varieties are superbi-partient (ratio of 5 to 3), supertripartient (ratio of 7 to 4), superquadri-partient (of 9 to 5), and so on. Thus the ratio of one and four-fifths to one is super-quadri-partient. According to Boethius, then, the intermediate ratios of one and two-fifths and one and three-fifths to one have no names. Some of his followers extend the name of superpartient to these, and some would invent the adjectives superbi-quintus and supertriquintus to signify them; other used superbi-partiens quintas and supertripartiens quintas. Multiple superparticular and multiple superpartient ratios have in the major term a multiple of the minor together with the fraction which gives the remaining adjectives. Thus, the ratio of $7\frac{1}{4}$ to 1 is multiple superparticular, being septuplus sesquiquartus; and $7\frac{3}{4}$ to 1 is multiple superpartient, being septuplus supertripartiens. The preposition *sub* serves as before, prefixed to *super*, to denote the inverse ratios. The reader may fancy for himself, if he can, the beauty of a treatise in which the ratio of 4 to 11 is expressed by *duplus subsupertripartiens*. Not that the writers of these works were ignorant of more simple phrases; and we remember one place in which the example of Aristotle is brought forward to show that it would not be wrong to use them.

Of means, or *medieties*, Boethius discusses ten, to which Jordanus added an eleventh. The first three bear the names which have descended to us, arithmetic, geometric, and harmonic; and all are as follow. Let a, b, c , be three numbers, of which a is the greatest and c the least.

1	$a-b : b-c :: a : a$	7	$a-c : b-c :: a : c$
2	$a-b : b-c :: a : b$	8	$a-c : a-b :: a : c$
3	$a-b : b-c :: a : c$	9	$a-c : b-c :: b : c$
4	$b-c : a-b :: a : c$	10	$a-c : a-b :: b : c$
5	$b-c : a-b :: b : c$	11	$a-c : a-b :: a : b$
6	$b-c : a-b :: a : b$		

The works of Boethius and his followers consist in dissertations on what would now be called the most obvious properties of the ratios of numbers, enriched with comments of every species, from numerical to

theological. It is not right that they should be utterly lost sight of; for they form a dark background on which the merits of Sacrobosco, Bradwardine, Regiomontanus, and afterwards Tonstall and Recorde, are very distinctly seen.

NUMBERS, FIGURATE and POLYGONAL. [NUMBERS, APPELLATIONS OF.]

NUMBERS OF BERNOULLI. This name is given to certain numbers (we here see the mathematical use of the word, for they are all fractions) first used by James Bernoulli, in his 'Ars Conjectandi.' They are in fact (though not so considered by Bernoulli) the co-efficients of the divided powers of x in $1 : (\epsilon^x - 1)$. We should hardly have given them a place here, as our list of such ultimate references in mathematics is by no means complete, if it were not that they only appear to a sufficient extent in one English work that we know of (Peacock's Examples). Let

$$\frac{1}{\epsilon^x - 1} = \frac{1}{x} - \frac{1}{2} + \frac{B_1 x}{2} - \frac{B_3 x^3}{2 \cdot 3} + \dots$$

a form which it is shown to take. Then $B_1, B_3, B_5, \&c.$, are what are called the numbers of Bernoulli, and the following list will show twenty-five of them, the first column being the index of B , the second the numerator of the fraction, and the third its denominator. As far as B_{20} , these are taken from Euler's Differential Calculus, all the rest (and the logarithms) from Grunert's Supplement to Klugel, which professes to take the additional numbers from a work of H. A. Rothes, and the logarithms from Eytelwein's work on the higher analysis:—

No.	Numerator.	Denominator.
1	1	6
3	1	30
5	1	42
7	1	30
9	5	66
11	691	2730
13	7	6
15	3617	510
17	43867	798
19	174611	330
21	854513	138
23	236364091	2730
25	8553103	6
27	23749461029	870
29	8615841276005	14322
31	7709321041217	510
33	2577687858367	6
35	26315271553053477373	1919190
37	2929993913841559	6
39	261082718496449122051	13530
41	1520097643918070802691	1806
43	27833269579301024235023	690
45	596451111593912163277961	282
47	5609403368997817686249127547	46410
49	495057205241079648212477525	66

Thus the coefficient of $x^{15} : 1.2.3 \dots 15$ in the development of $1 : (\epsilon^x - 1)$ is $3617 : 510$, or B_{15} . The logarithms of the first eighteen numbers are as follows:—

No.	Logarithm.
1	0.2218487496—1
3	0.5228787453—2
5	0.3767507096—2
7	0.5228787453—2
9	0.8794260688—2
11	0.4033154004—1
13	0.0669467896
15	0.8507783387
17	1.7401350433
19	2.7235576597
21	3.7918359878
23	4.9374188514
25	6.1539724516
27	7.4361345055
29	8.7792940212
31	10.1794459554
33	11.6330790754
35	13.1370898829

The higher numbers may be approximately verified by the following rule. Let π be the ratio of the circumference of a circle to its diameter; then

$$B_{2x-1} = 2 \frac{1.2.3 \dots 2x-1.2x}{(2\pi)^{2x}} \text{ nearly.}$$

We shall have some occasion to point out the uses of the numbers of Bernoulli in the article SERIES. The theory of these numbers will be found in Peacock's translation of Lacroix, Euler's 'Differential Calculus,' Lacroix's 'Differential Calculus,' 3 vols., and in a very elabo-

rate article ('Bernoullische Zahlen') in the work of Grunert already cited.

NUMBERS, THEORY OF. The theory of numbers is in fact the science of whole or integer numbers, and its most general problem is: "Given any equation whatsoever involving two or more unknown quantities, or any number of equations between a greater number of unknown quantities, to determine every possible solution in which the values of the unknown letters are whole numbers." It may also be considered that the science extends to the determination of all solutions which contain nothing but rational or commensurable fractions, all surd quantities or incommensurables being excluded. If, for example, the equation $x^2 + y^2 = 1000$ were to be solved, x and y being whole numbers or rational fractions, let the rational fractions reduced to a common denominator be $p : z$ and $q : z$; then the equation becomes $p^2 + q^2 = 1000 z^2$; and if all possible whole values of p, q , and z be found, all the fractional solutions of the former equation can be exhibited.

Connected with the science before us is a very large quantity of properties of numbers, of which it must be said that they can be proved easily enough, but cannot be explained. Usually, in retracing the steps of an algebraical demonstration, we can easily connect the result with common and self-evident notions, which seem both to justify the conclusion, to render it natural, and destroy much of the curiosity, and even interest, with which it is looked at by a person used to algebra, who hears of the conclusion for the first time. In the theory of numbers it seems to us that the curious character of the conclusions is not so much lessened by the demonstrations, and perhaps this may be the reason why the science becomes a sort of passion, as Legendre remarks, with most of those who take it up. The instances given by the writer just cited, in his preface, will show the sort of properties which we speak of. If c be any prime number, and n any other number not divisible by c , then $n^{c-1} - 1$ is always divisible by c . Then $2^6 - 1$, or 63 , is divisible by 7 . Again, if any prime number divided by 4 leave a remainder 1 , it is the sum of two square numbers: thus 13 is the sum of 9 and 4 , 17 of 16 and 1 , 29 of 25 and 4 , &c.

The theory of numbers is not of much immediate practical utility in the applications of mathematics, which generally involve continuously increasing magnitude, and in which therefore the introduction of whole numbers is matter of convenience, and not of necessity. Again, the data of such applications are usually only approximate, so that an answer in whole numbers, should such a thing occur, is not exact, and possesses no particular interest. Hence this theory is little studied by a very large class of mathematicians, among whom it is not uncommon to meet with a person deeply versed in the higher analysis, who does not even know the principal results obtained by Gauss or Legendre. The subject is, in fact, an isolated part of mathematics, which may be taken up or not, at the choice of the student. It may possibly at some future time be connected with ordinary analysis, that is to say, the determination of the integer solutions of a set of equations may not be so distinct a thing from that of a mere solution, integer or not, as it is at present. In fact, a hint given by M. Libri, in a tract presently to be cited, does give completely the means of assimilating the expression of a problem in this theory to that of one in ordinary analysis. Suppose, for example, it is required to solve in whole numbers the equation $x^2 + y^2 = x^3$. Let π represent two right angles; then it is well known that $\sin \pi x = 0$ when x is a whole number, and never else; so that "required a solution of $x^2 + y^2 = x^3$ in whole numbers" is precisely the same problem as "required any solution of the three equations $x^2 + y^2 = x^3$, $\sin \pi x = 0$, $\sin \pi y = 0$."

The earliest consideration of the theory of numbers may have been made in India [VIGA GANITA, in BIOG. DIV.]; but the earliest treatise is probably that of Diophantus, which consists of nothing else but problems of this science, inasmuch that the theory itself has been sometimes called the Diophantine analysis. The subject then rested, without making any progress, until the time of Bachet de Meziriac and Fermat, the editor and commentator of Diophantus. The subject rested again until the time of the man who literally left no part whatever of mathematics unaugmented, Euler. After him, Lagrange, Legendre, and Gauss applied themselves contemporaneously to this theory. The works of the two latter are the separate treatises on this particular science, in which the advanced mathematical student must look to know its present state. Various Memoirs of MM. Cauchy and Libri may also be mentioned; one in particular by the latter (in the 'Mémoires de Mathématique et de Physique,' vol. i., Florence, 1829), in which the subject is made to have more resemblance than usual to ordinary analysis. An elementary treatise on the theory of numbers, suited to the present state of the subject, is much wanted. The only one in English, that of Barlow, was published in 1811: it can be well recommended for all that it includes.

The 'Disquisitiones Arithmeticae' of Gauss (Brunswick, 1801) were translated into French by M. Pouillet-Delisle (Paris, 1807). The 'Théorie des Nombres' of Legendre (third edition, Paris, 1830) has the advantage of coming later than that of Gauss (which itself came after the first edition of Legendre's), and of using methods and notations which are more familiar to the mathematician. Both are works of great originality: that of the German is condensed, and full of historical information; that of the Frenchman easier to follow, but like most French works, deficient in precise historical reference. It is

not a little singular that the two great writers on this subject should have been the men who, independently of each other, introduced the method of LEAST SQUARES.

The beginner in algebra may obtain some command over equations of a simple character, not exceeding the second or third degree, by a method which is, we believe, due to Playfair, or which, at least, is published in the collection of his works. Let the equation be, for instance, $ay^2 + bxy + x^2 = z^2$, in which x , y , and z are to be whole numbers. Throw the equation into a form which admits of both sides being reducible into factors; for instance,

$$y(ay + bx) = (z - x)(z + x).$$

If then $z - x = vy$, we have $z + x = (ay + bx) : v$, which equations give

$$x = \frac{(a - v^2)z}{a - bv + v^2} \quad y = \frac{(2v - b)z}{a - bv + v^2}$$

Assuming v at pleasure, z may be easily taken so as to make both x and y whole numbers; and the same method will succeed in many equations.

Euclid's geometry, assuming only the use of his three celebrated postulates, enables him, a linear unit being given, to construct the length represented by any algebraical expression which involves only additions, subtractions, multiplications, divisions, extraction of the square root, or combinations of all these. But a cube or fifth root is beyond the power of the system. Again, from the theory of equations it is soon made obvious that the solution of the equation $x^n - 1 = 0$, and the division of a circle into n equal parts, are one and the same problem. One solution of the preceding is $x = \cos \theta + \sqrt{-1} \sin \theta$, where θ is the n th part of four right angles. [Root.] Euclid, in his fourth book, shows how to cut a circle into three, four, five, and fifteen equal parts; and analysis shows that the sines and cosines of the angles so involved can be obtained by formulæ which involve no roots except the square. But except into halves, thirds, fifths, or fifteenths, or parts obtainable from these by one or more bisections, Euclid was not able to cut a circle into equal parts.

So the matter rested for about 2000 years, until Gauss, in his 'Disquisitiones Arithmeticae' (1801), not only pointed out how to extend Euclid's conclusions, but also in a manner how to account for them. The statement of his results, even without demonstration, is instructive to the learner, and we shall give it accordingly: referring for the demonstration to the works of Gauss or Legendre, or to Murphy's 'Theory of Equations.'

The expression $a + \sqrt{b}$, a and b being rational, is the solution of a quadratic equation with rational co-efficients. But if a and b themselves have the form $c + \sqrt{d}$, in which c and d have themselves the same form, and so on; then $a + \sqrt{b}$ is the solution of a quadratic equation in which the coefficients are themselves the solutions of quadratic equations, and so on. Consequently, any equation, the root of which is capable of construction by Euclid's postulates, must be reducible to a system of quadratics; and the converse. Now if n be a prime number, $n - 1$ is an even number, and therefore has factors. Let its prime factors be $2, a, b, c$, &c., and let them severally enter p, q, r, s , &c., times: so that

$$n - 1 = 2^p a^q b^r c^s \dots$$

Gauss succeeded in showing that when n is a prime number, the solution of the equation $x^n - 1 = 0$, can be made to depend upon the solution of p equations of the second degree, q of the a th degree, r of the b th degree, and so on. Consequently, whenever 2 is the only prime factor of $n - 1$, or when $n - 1 = 2^p$, n being prime, or when $2^p + 1$ is a prime number, the solution of $x^n - 1$ is reducible to that of p quadratic equations, and the division of the circle into n equal parts can be accomplished by Euclid's geometry. And further, it is easily demonstrated that $2^p + 1$ can never be a prime number, except when p itself is a power of 2 (2^n included) though $2^p + 1$ is not then always prime. Nor has it been shown that other divisions are impossible: Gauss's theorem merely points out cases in which the thing can be done, without pronouncing the exclusion of others. Gauss, indeed, does assert that he can demonstrate all other cases to be impossible to be constructed by geometry, that is, reducible to quadratic equations: and the thing is highly probable. If we now construct the series $2^1 + 1, 2^2 + 1, 2^4 + 1, 2^8 + 1$, &c., among which all our chances lie, we have 3, 5, 17, 257, 65537, 4294967297, &c. The first five are prime numbers: Euclid has disposed of the two first divisions; Gauss has added that a circle can be geometrically divided into 17, 257, and 65537 equal parts. But 4294967297 is not a prime number, being divisible by 641.

NUMBERS, THE BOOK OF, one of the books of the Pentateuch. In Hebrew it has two titles, *בְּרֵאשִׁית*, and *he spake*, which is the first word of the book, and *בְּמִדְבָּר*, in the desert, which is the fifth word in the first verse, and which applies to the whole book, inasmuch as the events which it records took place in the desert. Its title in the Septuagint is *Ἀριθμοί*, Numbers, because it contains the censuses of the people of Israel (chaps. i.-iii., and xxvi.).

The first four chapters of this book consist of separate accounts of commands given by God to Moses, while the Israelites were encamped at the foot of Sinai, respecting the census and the classification of the people, and the duties of the priests and Levites. The succeeding

chapters (v.-x. 10) contain various laws, most of which are additions to those before given in the books of Exodus and Leviticus; and the rest of the book is occupied with the narrative of the journeys of the Israelites, from the time of their leaving Sinai to their second arrival at the Jordan, and their encampment in the plains of Moab. The time over which the book extends is from the first day of the second month of the second year after the departure from Egypt, to the first day of the eleventh month of the fortieth year of the same epoch. This part of the book also contains various enactments.

We learn from the last verse of the last chapter that this book was written by Moses "in the plains of Moab by Jordan near Jericho," and consequently just before his death. Vater has attempted to show that it is composed of short narratives written by different persons (vol. iii., p. 452, &c.), and De Wette adduces several passages which appear to disagree with each other, and with the parallel passages in the book of Exodus ('Lehrbuch d. Hist. Krit. Einleitung in d. A. T.'). but the more carefully the facts and allusions contained in it are examined, the more satisfactorily they confirm the belief that it, as well as the other books of the Pentateuch, was the production of Moses, and its genuineness rests upon the same points of evidence as to its origin and its historical truth as the other books. Even De Wette admits that parts of it belong to the Mosaic age.

This book is quoted or referred to in the New Testament (compare Numb. xx. 11 with 1 Cor. x. 4, and Numb. xxi. with John iii. 14). The passage in chap. xxiv. 17-19, is generally understood as a prediction of the Messiah.

(Rosenmüller's *Scholia in Vet. Test.*; the *Introductions* of Eichhorn, Jahn, De Wette, and Horne; Graves's and Vater's *Commentaries on the Pentateuch*.)

NUMERAL CHARACTERS. There are three simple and obvious modes of constructing symbols of number. 1. By arbitrary invention. 2. By the choice of letters of the alphabet. 3. By a system of repetitions of a single unit, as I, II, III, IIII, &c., with marks of abbreviation. Some may doubt whether the first and third were ever really employed; but it is not known that we can assign to the Indian numerals any other origin than the first, and the third explains the Roman system with a degree of consistency which is most extraordinary, if it be only accidental coincidence.

Distinct numeral characters are found to have existed or to exist among the Chinese, Indians, and Arabs, &c., Phœnicians, Palmyrenes, Hebrews, Egyptians, Greeks, and Romans; and others are given as in ancient use among the Mexicans. We shall here confine ourselves to the simplest explanation of those systems which will be wanted by the student of ancient literature. Of these, as it should seem, the Indian system may belong (though it may be doubted) to the first class; the Hebrew and the common Greek system to the second; the Roman, Phœnician, Palmyrene, ancient Greek, Egyptian, and Chinese, to the third class.

The system received from the Hindus through the Arabs, and now adopted throughout Europe, has been gradually much altered in the forms of the symbols. The symbols we now use, especially in their old manuscript forms, 1, 2, 3, 4, 8, may be explained with reasonable probability upon the third system; but not 5, 6, 7, 9. [ARITHMETIC.]

The Hebrews used the letters of their own alphabet, giving the finals a separate and particular value, as follows:—

Letter	א	ב	ג	ד	ה	ו	ז	ח	ט	י
Numeral Signification	1	2	3	4	5	6	7	8	9	10
	כ	ל	מ	נ	ס	ע	פ	צ	ק	
	20	30	40	50	60	70	80	90	100	
	ר	ש	ת	ך	ם	ן	ף	ץ		
	200	300	400	500	600	700	800	900		

The use of the final letters as signifying numbers is of newer date than the rest; the old system required the junction of subordinate numbers to express 500, 600, &c. Numbers not expressed above were made by juxta-position of letters denoting other numbers, according to a decimal subdivision, as among the Greeks; the only exception being 15, which, as 10 + 5 or *יה* made a word signifying the Creator, they wrote as 9 + 6, or *טו*. In a language like the Hebrew it would be impossible to prevent every combination of numbers from also standing for a word or words; and the Oriental nations accordingly have frequently expressed dates by sentences. Thus "Hooshung Shah is no more," rendered into Persian, expresses, in the numeral force of the letters, the year 837 of the Hegira, the date of the death of that prince.

The Greeks, in some enumerations, have three distinct methods of expressing numbers; but the first of them, which consists in the use of the letters of the alphabet to denote the successive books of a work, as in the 'Iliad,' is as much a method of naming as of counting. Something more to the point is the old system which occurs on inscriptions, in which the unit is represented by a single mark, five by *Π* (the initial of ΠΕΝΤΕ), ten by *Δ* (that of ΔΕΚΑ), and 100 by *Η* (that of ΗΕΚΑΤΟΝ). And in all cases five of any symbol are written by inclosing the symbol in *Π*: thus *Δ* is five tens, and *Η* is five hundreds. Thus 879 is *Η* *Η* *Η* *Δ* *Δ* *Π* *Π* *Π* *Π* *Π*. This ancient Greek method, as found on inscriptions

(which, according to Heilbronner, is alluded to in a written work by Herodian only), is supposed to be as old as the time of Solon. The Egyptian hieroglyphic system is on the same principle, but without abbreviations; the symbol of ten resembling that just given for five.

In describing the later Greek notation, we leave out of view the extensions made by the mathematicians, the principle of which is described in ARITHMETIC. It appears most distinctly that the system was made either at a time when the Greek alphabet was in possession of more letters than it permanently retained, or that it was introduced into Greece by communication with some nation (the Phœnician, perhaps) which had some additional letters. The *Vau* of the Hebrew and Phœnician, which stands for six, and is wanting in the Greek alphabet, appears in the Greek numeral system under the name of *ἐπίσημον βαυ*, and is expressed by a symbol resembling ϵ , not very unlike the *Vau* turned the other way. The *Koph* and *Tsaddi* appear under the names of *ἐπίσημον κοππά* and *ἐπίσημον σανπι*, with symbols expressed in our types by ζ and θ ; but the former is one behind its place in numeral signification, being 90 among the Greeks and 100 in the East: the latter takes the same numeral place as the final *Tsaddi* in the Hebrew system. The word *air* will be a useful guide to the letters beginning the several scales, as follows:—

Letter	α	β	γ	δ	ϵ	ζ	η	θ
Numeral Signification	1	2	3	4	5	6	7	8
	ι	κ	λ	μ	ν	ξ	$\omicron$	π
	10	20	30	40	50	60	70	80
	ρ	σ	τ	υ	ϕ	χ	ψ	ω
	100	200	300	400	500	600	700	800
	α_1	β_1	γ_1	δ_1	ϵ_1	ζ_1	η_1	θ_1
	1000	2000	3000	4000	5000	6000	7000	8000

The Roman notation, including all the varieties which occur in printed works, is as follows:—

1 I	50 L
2 II	60 LX
3 III	70 LXX
4 IIII, IV	80 LXXX, XXC
5 V	90 LXXXX, XC
6 VI	100 C
7 VII	200 CC
8 VIII, IIX	300 CCC
9 VIIII, IX	400 CCCC
10 X	500 D, I ζ
11 XI	600 DC, I ζ C
12 XII	700 DCC, I ζ CC
13 XIII, XIIV	800 DCCC, I ζ CCC
14 XIIII, XIV	900 DCCCC, I ζ CCCC
15 XV	1000 CI ζ , M, ∞ , I
16 XVI	2000 CI ζ CI ζ , IICIC, IIM
17 XVII	
18 XVIII, XIIIX	5000 I ζ ζ , V
19 XVIIIII, XIX	10000 CCI ζ ζ
20 XX	50000 I ζ ζ ζ
30 XXX	100000 CCCI ζ ζ ζ
40 XXXX, XL	1000000 CCCCCI ζ ζ ζ

The grammarian Priscian would have it that I denoted unity, because the Greek word *μια*, with μ cut off, has ι for its first letter; that V is five, as being the fifth vowel, and X ten, as being the tenth consonant, of the Greek alphabet. Any explanation of this system which endeavours at an alphabetical deduction must, as far as has yet been seen, fail entirely in giving a probable origin. The following scheme, however, contains suggestions of some antiquity, and certainly, as before remarked, is either a true explanation or a most extraordinary coincidence. The account of it was revived in our day by Leslie, in

I	II	III	IIII		IIIIIIII	X	↵

							r

an article in the 'Edinburgh Review,' and afterwards in his 'Philosophy of Arithmetic.' But it may be found almost entire in the 'Cursus Mathematicus' (1690, vol. i., p. 28) of Dechales, who gives it as the opinion of several of his time. And the earliest hints (by no means complete, and mixed with some absurdities) which we have found are in the 'De Numeris Libri Duo' of John Noviomagus, Paris, 1539, 8vo.

Imagine a person used to decimal counting by means of the fingers having recourse to simple counting by making a mark for each successive unit, as in *a*, *b*, *c*, &c. At ten he might be expected to make some symbol that his *handful* was completed, and the drawing a mark through the whole ten unit symbols, as at *e*, would do very well. This he might abbreviate, as at *f*, retaining only the symbol of a unit

and that of the line drawn across. The handful of tens, or one hundred, might be represented by retaining only the unit symbol and two ligatures, namely, that of the tens and that which made all the ten tens into one symbol, as at *g*. The ten hundreds would require a unit with three ligatures, or four strokes altogether, which, if they were written without taken the pen off, might be made as at *h*, which might degenerate into *k*, and finally into *l*. Again, by cutting *l* into two halves, we have *m* or *n*, which might suggest themselves as proper representatives of half a thousand, or five hundred. Similarly, bisection of *f* and *g*, or of *o* and *q*, would suggest *p* and *r* as proper symbols for the halves of ten and one hundred. The symbol *a* has a resemblance to I, *f* to X, *g* to C, *h* to M, *m* to D, *p* to V, and *r* to L.

We cannot find any precise information upon the time of the commencement of the principle of local value which prevails to a certain extent throughout the Roman system,—namely, that a smaller symbol before a larger one, in numbers less than one hundred, denotes a subtraction, after it an addition. This principle does not appear in the Phœnician or Palmyrene notations, which otherwise much resemble the Roman in their principle of notation, though they approximate to pure vicenary scales, both adopting distinct symbols for twenty.

The Chinese use three systems: the first, not very simple, and ancient; the second, intentionally complicated, and employing symbols of words to denote numbers, is introduced in deeds and other instruments, to render alteration difficult; the third, a simplification of the first, supposed to have been made by the Jesuit missionaries.

For further information on the subject of this article, with abundant references, see the article 'Arithmetic' in the 'Enclopædia Metropolitana,' by Dr. Peacock.

NUMERATION is a term generally applied to the art of representing numbers by distinct names and symbols, a sense in which the word is used by the oldest writers. Every treatise on arithmetic must necessarily begin with something on this art of counting and representing the results of counting, on the goodness of which, slight and easy as any method may appear to which we have been habituated from childhood, the progress of the arts of life, to say nothing of the mathematical sciences, is in no slight degree dependent. The time is gone by for a formal eulogy upon the benefits of any fundamental method of expression; we will therefore content ourselves with quoting a part of that which is found in the first English work on arithmetic, Robert Recorde's 'Grounde of Artes' (1540). We quote this also because it is an instance (the only one we ever met with in a mathematical work) of the species of doggerel comic verse afterwards in use on the stage (see the 'Comedy of Errors'), which has a sort of measure and rhyme, though printed in the form of simple prose in the work from which we cite (we put the syllables which are meant to rhyme in italics):—"Master. Wherefore in all great workes are clerks so much desired? Wherefore are auditors so richly fed? What causeth geometicians so highly to be *inhaused*? Why are astronomers so greatly *advanced*? Because that by number such things they *find*, which else would far excel man's *mind*. . . . Master. Exclude number, and answer to this question: How many years old are you? Scholar. Mum. Master. So that if number want, you answer all by *mummes*? How many miles to London? Scholar. A poak full of *plums*. . . . Master. If number be lacking, it maketh men *dumb*, so that to most questions they must answer *mum*. Scholar. This is the cause, sir, that I judged it so *vile*, because it is so common in talking every *while*; for plenty is not dainty, as the common saying is. Master. No; nor store is no sore, perceive you *this*? The more common that the thing is being needfully *required*, the better is the thing and the more to be *desired*. But in numbring, as some of it is light and *plain*, so the most part is difficult and not easie to *attain*."

The earliest method of signifying a large number must have been such a one as the scholar uses above, when he designates a large number of miles as a "poak full of plums," namely, the similitude of some visible or well-known collection of units. The fingers of the hand, or of both hands, or the united number of fingers and toes furnished natural collections of reference on which the various quinary, decimal, and vicenary scales in existence have proceeded. The transition from counting by tens to counting by dozens might have been caused by the facility of subdivision which the number twelve possesses, though we rather doubt this explanation, at least unless we assume that the division of the Roman *As* into twelve *uncia* is to be explained on the same principle. From this we think came the method of reckoning by dozens to be introduced throughout Europe, as would that by thirteens, if the Roman coin or weight had been so divided.

Our present numerative system is stated by writers to employ the words unit, ten, hundred, thousand, million, billion, trillion, quadrillion, quintillion, sextillion, septillion, octillion, nonillion, &c. But the greater part of this is pure statement; for the terms billion, trillion, &c., though defined by arithmetical writers, have never found their way into common use, the want of such large numbers having never been experienced. The French indeed have naturalised the term *milliard*, meaning one thousand millions, in matters of public debt and revenue, which only shows how little the term *billion* has been used among them, since, according to their writers, the *milliard* and *billion* are the same things. Tonstal expressly says, that in his time (Henry VIII.) the common reckoning from millions was made by millions of millions, &c., and the word *millio* is noted as a vulgarism

by him (neither is it among the recognised barbarisms of Ducange). Recorde uses nothing more than millions repeated; so that it seems the billions and higher denominations were never anything but a fancy of arithmetical writers, conceived after the time when elementary works ceased to be written in Latin. The probability of this is increased by their meaning different things in different countries: with us the billion is a million of millions, a trillion is a million of billions, and each denomination is a million of times the one preceding. With the French and the other Continental nations (except some of the older writers, at least, among the Italians), the billion is a thousand millions, and each denomination is a thousand times the preceding. According to English writers, the number 1,234,567,891,234,567,891 is one trillion, 234,567 billions, 891,234 millions, and 567,891; according to the French writers, it is one quintillion, 234 quadrillions, 567 trillions, 891 billions, 234 millions, 567 thousands, and 891. For common purposes, the denominations higher than a million may be abandoned, it being remembered that all the figures on the left, after six are taken off on the right, are so many millions, and all above twelve figures so many millions of millions. In writing, round numbers of millions should be written as such; thus, 638 millions, not 638,000,000: in computation it is of course a different thing. Some authors seem to think it very scientific to parade ciphers, sometimes by the dozen; and so it is, no doubt, since it shows they know how many ciphers go to a million or a million of millions; but no reader likes to stop and examine 000,000,000,000, when the words "million of millions" would have done equally well.

The decimal system, made complete, supposes a point always to be placed at the end of the units, to separate them from the fractions which may follow. When there are no fractions, the point is useless, as in 675 or 675.000, which is 675. The numbers on the right of the point, successively denoting tenths, hundredths, thousandths, &c. of a unit [FRACTIONS], are in denominations which have not received distinct names. The modern French call them decimes, centimes, &c.; and the attempt has before now been made (see Wybald's 'Tactometria' 1650) to introduce centesms, millesms, &c. into English, but with no success.

The principle of *local value* [ARITHMETIC], which distinguishes our system of numeration from that of the Greeks and Romans, is applicable to any system, whether decimal or not. If 10 stands for *ten*, that is, if its units in the second column are ten times in value those of the first column, nine numeral symbols besides the cipher are requisite; but if 10 had signified fifteen, it would have been necessary to have fourteen distinct symbols of number besides the cipher, since 10, 11, &c. now stand for sixteen, seventeen, &c. In such an explanation, the frame-work of our numerical language (being decimal) is not well calculated to give an easy comprehension of the change: we should rather invent a word for fifteen, or five and ten, say *A*; whence *A*-one, *A*-two, &c. would be the spoken sounds answering to what we now call sixteen, seventeen, &c.; while ten, eleven, twelve, thirteen, and fourteen would require new names not connected in etymology with *ten*.

The method of reducing a number, decimally expressed, to another in which the *radix* or base of the system (as ten is that of the common one), is *a*, is as follows: divide the number successively by *a*, expressed in the decimal system; the remainders give the units, *as*, *aas*, &c. of the new expression. Thus if 12376 is to be expressed in the *quinary* system, whose base is 5, we should have the following process:—

5)12376 Rem.	Number required,
5)2475 1	344001.
5)495 0	Decimal.
5)99 0	$3 \times 5^5 = 9375$
5)19 4	$4 \times 5^4 = 2500$
5)3 4	$4 \times 5^3 = 500$
0 3	$1 = 1$
	12376

This exhibits both the reduction to the quinary system and the restitution of the decimal expression; but if the number had been given in the quinary system, it might have been reduced to the decimal system by the same rule, the new base ten being, in the old or quinary system, represented by 20, and the rule of division being performed by the use of five in the same manner as ten is used in the decimal system.

20)344001 Rem.	Number required,
20)14422 11 or 6	12376.
20)443 12 or 7	Decimal. Quinary.
20)22 3	$1 \times (10)^4 = 310000$
20)1 2	$2 \times (10)^3 = 31000$
0 1	$3 \times (10)^2 = 2200$
	$7 \times 10 = 240$
	$6 = 11$
	344001

The quinary being supposed the old system, as soon as we come to the remainder 11, we have to invent a new symbol (say 6), since 11,

in the *new* system, is to stand for eleven. For further examples, see the 'Library of Useful Knowledge: Treatise on the study of Mathematics.'

In teaching the elements of numeration by the abacus [ABACUS], it is desirable that exercise should be given in several different systems, were it only to prevent the formation of that impression which so many students long retain, that the decimal system is natural and necessary. The want of words for the denominations will be the only difficulty; this may be got over by using the letters A, B, C, &c., to represent them. Thus if the system be quinary, A counts as one ball on the second row or five on the first, B as one ball on the third row, five on the second, or twenty-five on the first, and so on. All the balls on the second row may be marked A, those on the third B, &c.

NUMERATOR (or numberer), the part of a fraction which states how many of the aliquot parts of a unit are taken, such as are described by the denominator. Thus $\frac{3}{7}$ being three, not of units, but of sevenths of a unit, 3 is the numerator.

NUMERICAL, as opposed to literal, in algebra, applies to an expression in which the coefficients of a letter are all numbers, and not letters. As opposed to algebraical, it applies to the magnitude of a quantity, considered independently of its sign. Thus -7 is said to be numerically greater than -5, though algebraically less. [NOTHING.]

NUMERICAL DIFFERENCE. (Logic.) Down to our own time, logicians have distinguished one individual as differing *numerically* from another, when both belong to the same species: thus one horse is said to differ numerically from another. The idiom has never found its way into common language, though given in our old dictionaries. Nor is this to be wondered at, for number in English is multitude; and two regiments may differ numerically, but two men cannot.

The wrong use of the English adjective arises from the Greek word *ἀριθμός*, which is used for the result of counting, being supposed to signify the multitude counted. This it did only in the sense in which *summa* (sum) came to signify multitude in English: thus 10 is a *sum*, of which the *unitas summa* is *unitas decima*. The difference is, that the word *sum* never had any other sense in English: while in Greek it never lost its first meaning, that of the item of enumeration. Thus *οἱ ἀριθμοὶ τοῦ σώματος* meant the limits of the body: Herodotus cannot tell what multitude (*πλήθος*) each nation furnished to the enumeration (*ἐς ἀριθμόν*). And Aristotle distinctly lays it down that *μονάς* and *ἀριθμός* differ neither in *quantity* nor in *quality*: meaning that the thing which is *μονάς* when it stands alone becomes *ἀριθμός* when it stands in an enumeration as one of the items. Hence the Greek logicians could properly say that though a horse and a sheep differ *εἶδει* (in species), one horse and another only differ *ἀριθμῶ* (as different items of one species). The word *monadic* would be better than *numerical*, for logical use. See more details in the 'Transactions of the Philological Society.'

NUMISMATICS. The term numismatic, derived from the Greek *νομισμα*, is applied to the study of ancient and modern coins. By the writers of the 15th and 16th centuries it was called the science of medals. It divides itself into the following principal branches:—The study of coins considered in reference to the monetary systems to which they belong, or the study of the historical, mythological, and geographical allusions of inscriptions and types, and the discrimination of true ancient coins from modern imitations or forgeries. So vast is the extent of the subject that a perfect knowledge of all branches has never been attained by one individual. The value of ancient coins to the study of geography, history, and philology is considerable, for as they are monuments issued by public authority it must be assumed that the information they convey is correct; and they consequently offer many corrections to the orthography, in some instances they rectify the chronology, and even add to history and geography names which have disappeared from literature. Considered in reference to the arts they are valuable as showing their state at different fixed periods, while they present invaluable portraits of princes and illustrious personages, valuable representations of temples, statues, and localities, and important hints as to mythology and historical events. The study of them is however generally subjective, and they require elucidation from rather than give it to literature. In some instances indeed they hand down the knowledge of obscure sites, or give a clue to the history of dynasties which have not been recorded on the pages of the historian. As religious monuments they transmit a history of the local deities, and representations of their shrines and statues and the religious ideas of the age in which they were struck, and they afford considerable insight into the autonomous or free, and imperial administrations of states and cities, and their political changes, monetary systems, and dialects. But their great charm is their being monuments of ages long past, ancient pictorial illustrations of classical authors, undeniable evidences of a past state, and links which connect the familiar coins of the day with the first struggles of invention and the development of monetary systems. At the same time they are a most microscopical branch of archaeology.

There can be little doubt that the Romans made collections of ancient coins, from the price paid for remarkable forgeries and the fact of their being inlaid and valued during the lower empire as gems by the laws. Petrarch, in 1374, was the first in the middle ages to collect them, Alphonso, king of Arragon, and Cosmo di Medici continued in the next century to do the same, and in the 16th

century the study had so progressed that 200 cabinets were known in Holland alone. In the 15th century they were first introduced into literature by Angelo Poliziano, in 1490; and a series of writers the chief of whom were Fulvius, A.D. 1500; Mazochi, A.D. 1526; Veio, A.D. 1560; Golzius, A.D. 1526-83; Agostino, A.D. 1586; Ursinus, A.D. 1600; and Patin, A.D. 1633; wrote chiefly upon and illustrated the imperial Roman series. In England the study commenced with Speed, A.D. 1522, and Camden, in 1586. The works of this century are not remarkable for their accuracy, and it is not till the following that the study of numismatics began to acquire the rank of a science. Frölich, Corsini, and Cary availed themselves of medals to write history of the Bactrian, Armenian, and Bosphoran princes; but the most remarkable writers of the 17th and 18th centuries were Morell, A.D. 1703; Vaillant, A.D. 1706; Spanheim, A.D. 1664; Pellerin, A.D. 1782; Hardouin, in 1729; Patin, in 1695. In the 18th century the critical Eckhel completely reformed the study of numismatics, A.D. 1787-1808, while Mionnet, in 1770-1842, gave a complete list of Greek coins, and Rasche, a lexicon of important use for the study.

Important contributions to the study of Greek numismatics have been added by Millingen in 1831, 1837, 1841; by Barthelemy, in 1821; Böckh, in 1821; and others. The study is still kept up by four numismatic journals. The Numismatic Chronicle in England, commenced in 1836, the 'Revue Numismatique' of France commenced at the same period, that of Belgium started in 1843, and the 'Numismatische Zeitung' of Weissensee in 1834.

The origin of the currency is traceable to the Greeks alone; the Egyptians used rings of metal, and perhaps scarabæi; the Assyrians had no coins; and the Jews and Phœnicians at an early period were equally destitute of stamped money. The honour of this invention was disputed by the Greeks themselves. The Lydians, Hermodice the wife of Midas, Aryandes, Theseus, Itonus of Thessaly, the Naxians, and Pheidon of Argos, B.C. 895 or 772, were said to have invented the art. Opinions generally incline to Pheidon, from the rude antiquity of the Æginetan coins; but the dispute refers to the metals. At Athens and in Greece Proper gold was not struck till B.C. 440, the gold coins in circulation being darics, Cyzicene staters, and ingots. While, however, the oldest examples of the gold currency are Asiatic, the earliest silver was undoubtedly struck in the Isles and the Peloponnese, as is shown by the archaic coins of Ægina, Rhodes, Thasos, Thebes, and other cities of Greece. The earliest coins were chiefly didrachms, tetradrachms, and drachms, few pieces of smaller denomination having been struck.

Little or nothing is known about the Greek mint: that at Athens was called the *Arxyprokeion*; dies were called *kommata*. The coins were always struck, never cast, under the authority of eponymi. The names of engravers occur on coins during the most flourishing period of the art; after the time of Alexander, in some rare instances, with the form ΕΠΟΙΕΙ assumed by artists of the later schools, as ΝΕΥΑΝΘΟΣ ΕΠΟΙΕΙ. 'Neuanthos was making it' on a coin of Aptera, and Theodotos on a coin of Clazomenæ. This form is however often omitted, and the name of the artist put by itself, generally in the nominative. They are distinguished from those of magistrates by being in smaller letters, and occupying less prominent positions, being often placed in obscure places, as on the attire, on the adjuncts, amidst the type, so as not to intrude too prominently on the eye. The name of Aristobulus is placed on a gold coin of Lysimachus; that of Zoilos on a coin of Perseus. The dekadrachms and later coins of Syracuse have many artists' names, as Eumenes, Eucleides, and Cimon, and others; and in Magna Græcia are those of Augeas, Philistus, and others. Some worked for more states than one, as Parmenides, who engraved coins of Syracuse and Neapolis; Aristippus, who did so for Heracleia, Metapontum, and Tarentum; and this branch of the art was pursued by gem-engravers, the name of Phrygillus, known from a cameo, also appearing on the coins of Syracuse.*

The use of gold coins in Asia Minor is as old as that of silver in Greece Proper, and coins have been found which can be attributed to the age of Croesus or Alyattes. Gyges, indeed, is stated to have used *oboloi* or spikes of this metal in the place of coins; and Croesus himself presented plinths or ingots of gold to the shrine at Delphi. Talents of gold are mentioned by Homer. In Greece Proper the issue of gold is of later date, probably not older than that of Philip II. of Macedon. At the time of Herodotus its value to silver was as 1 to 13; but in the days of Plato and Alexander it had sunk as 1 to 12; but the gold of the Darics, on account of its extreme purity, was as 1 to 15; while that of Cyzicus, owing to alloy with silver, was only as 1 to 14. The gold unit was the stater, or sovereign, equal in weight to two Attic drachms, or 132.6 grains, called also the *chrysinos*, gold piece, or the Philippos, Philip. At Athens itself gold was not struck till the archonship of Antigonus, B.C. 407 (Ol. xciii. 2), when the golden Victories were melted down for the purpose; and prior to that period Phœcean or Cyzicene staters were current in the city. ('Böckh in Cavedoni'; 'Ant. monet. d'Athene,' 8vo, Mod., 1836.) The Attic staters have the head of Athene and the owl, besides which there is an archaic *hekte* of 21.6 grains, having an owl and incuse square. It has been attributed to the city, but it was probably struck in Asia Minor.

* Brunn, Geschichte der Griechischen Kunstler, 8vo, Braunsch., 1856, II. p. 414.

In the French collection, however, there is a complete sequence of Attic gold coins, consisting of a stater, drachm or hemistater, triobolon, diobolon, obolos, and hemiobolon, supposed to have been issued about the time of Pericles; gold obols of Argos, of 16.5 grs.; triobolon of Carystus, with head of Hercules and a bull, of 49.3 grs.; others of Aetolia, on the Attic standards, a triobolon of Boeotia, of 59.75 grs., and a drachm of Acarnania, are known. But the principal ancient gold coins are, the Daric, of 129 grs., with an archer and incuse square, worth 15-20 Attic drachms—the coins with which the Persians bribed the orators of Athens and Boeotia; the stater of Cyzicus, worth (B.C. 358) 28 Attic drachms, and mentioned as the monthly pay of a soldier by Xenophon, with the adjunct of a fish as its normal type; the stater of Phocæa, of 138 grs., and distater of 276 grs., and submultiples, tetarte 4th, hekta $\frac{1}{2}$, and hemihekta $\frac{1}{4}$, worth 8 obols; staters of Lampsacus, with the head of Poseidon or Priapus, and the winged sea-horse, of 129 grs.; and at Cyrene, gold octodrachms or tetrastaters, and the large issues of staters and its multiples by Philip II. and his successors, on a standard of 133 grs.; and the large gold dekadrachms, tetradrachms, pentadrachms, and other pieces of the Ptolemies. Many of these later pieces of Ionia, in the finest style of the art, are of electrum, and were issued as submultiples of an electrum stater. The largest piece was the 16-staters of Lysimachus.

The Greek autonomous silver coins have been divided into three periods, the first from B.C. 895 to 471, from Pheidon of Argos, or the Lydians, to Alexander I., of Macedon, the type simple and monstrous, often only animals, inscriptions short and monosyllabic, pieces thick and globular, engraved rings like borders of Etruscan scarabæi, the reverses with hollow squares made by striking on a jagged die. 2. From Alexander I., B.C. 478, to Philip II. the art is much improved, the shape flatter and thinner, the inscriptions more complete, types are introduced on the reverse in the hollow square, which disappears under Amyntas III., B.C. 371; the types are surrounded by an engraved ring. 3. From Amyntas III., to B.C. 100, about 300 years, the finest period of the arts, types on obverse and reverse complete, the age of Phidias, Zeuxis, Polygnotus, and Praxiteles, names of magistrates and engravers appear; portraits are introduced by the successors of Alexander the Great. This is also a great epoch for gem engraving. Greek gold and copper coins fall into this period. 4. With the rise of the Roman power the gold and silver disappear, a few imperial mints, such as Cæsarea in Cappadocia, Antioch, Amisus, and Tarsus alone continuing to have the privilege of striking either Roman denarii or larger pieces till the time of Hadrian. The mint of Alexandria struck silver or potin, till the time of Gallienus. The letters follow the rule of inscriptions, the titles are pompous. In this last period only copper was coined with the name of the cities.

The principal coins which have been found are, the dekadrachms, or large silver coins of Athens; the dekadrachms, or Syracusan medallions; octodrachms of Macedonia, the Athenian tetradrachms, called the stater or Atticus—a long series extensively imitated by other cities and by princes; the didrachms of Ægina and Corinth; the drachms used all over Greece and Asia Minor; the tetrobolon or $\frac{2}{3}$ drachm; the triobolon, or hemidrachm; the diobolon, or $\frac{1}{2}$ drachm; the trihemiobolon $\frac{1}{4}$ drachm; the obolos, or $\frac{1}{8}$ drachm, struck by cities prior to the introduction of copper; the hemiobolon, or $\frac{1}{12}$ drachm; and the $\frac{1}{4}$ obolos, or $\frac{1}{24}$ drachm; and $\frac{1}{8}$ obolos, or $\frac{1}{48}$ drachm, the smallest of all silver coins struck at Athens. In the Attic standard, the drachm weighed 67.377 grs., and the tetradrachm 269.508, and of this coin, the dollar of antiquity, called the *γλαύξ λαυριωτική*, or 'Laurian owl,' from the mines of silver, and the type, 4 went to the gold stater, or chrysos; 25 to the mna, and 150 to the talent. Of these tetradrachms, which are the monetary standard of measure of antiquity, there are two types, the archaic coin, with the head of the archaic Athene, and the reverse an owl and olive-branch, which continued till almost the age of Alexander; and those of later than his reign with the helmed head of Athene of Pheidias, and the owl on an amphora, with the names of the three magistrates. These continued till the age of Mithridates, and even of the Romans.

In all the transactions of commerce, the drachm was the unit of value; the Attic standard was used at Corinth, Acarnania, Amphilo-chia, Leucadia, Epirus, Acanthus, Sicily and Cyrene; but under different forms, the Athenian coin was the tetradrachm, the Corinthian the didrachm—higher values are abnormal exceptions. The other standards were the Æginetan, consisting of 96 grs., introduced by Pheidon, from some Phœnician source, and the didrachms stamped with a tortoise which were called *chelonai*, tortoises, or *pacheiai*, thick, by the Athenians; they prevailed in Boeotia, Arcadia, Elis, Sicyon, Argos, Eubœa, Locris, and some of the isles. The other principal drachm was the Macedonian of 58 grs., which was used till the time of Alexander the Great, who substituted the Attic standard. Of Chios, there were pentadrachms, of 236 grs., supposing the drachm to have been about 47 grs. But the fact is, that it is still requisite to study the monetary history of each Greek state *per se*, as the currency was always slightly changing according to political circumstances and the rate of value, and the ancients had not probably the trial per pyx, or even a very accurate manner of determining the weight of their pieces, the irregular shapes of which offered tempting facilities for filing or paring.

The copper currency was the last introduced into Greece, and its appearance was not well received, it was first issued at Athens in the

archonship of Callias, B.C. 406, and the orator who recommended it went by the nickname of the Coppersmith. The oldest dated copper coins are those of Æropus II., king of Macedon, B.C. 399; and the necessity of change diffused its use, and it ultimately superseded, or was current with all denominations as high as the obolos. The principal bronze coins are the obolos, worth $1\frac{1}{2}d.$, the *chalkous*, or $\frac{1}{2}$ of an obolos, and the lepton, $\frac{1}{4}$ of a chalkous: there were subdivisions of the $\frac{1}{2}$, $\frac{1}{3}$ of an obolos, and pieces of 2 oboli, worth $3\frac{1}{2}d.$ Besides the oboli, there was an assarion worth $\frac{1}{10}$ of a denarius, and two other copper coins called the symbolon and kollybos, the value of which is unknown. Some of the monetary systems named the copper currency after the silver, and struck drachms, and didrachms and tetradrachms in this metal. Under the Roman empire, the copper currency was left to the care of the Greek municipalities, but after the national bankruptcy this was suppressed, and the copper issued only by the imperial mints. In the days of the republic, some of the states of Magna Græcia and Sicily used the Roman standard of the *as* and its subdivisions.

The types of the Greek coins had a religious aim, and either alluded to the eponymous deity, or some local tradition: their meaning was strictly religious. On the earliest coins the types consist of a single emblem, generally an animal or vegetable, placed upon one side only: as the tortoise on the coins of Ægina, the dolphin on those of Thasus, the vine-leaf on Camirus. Some pieces were familiarly known by the names of their types; thus the drachms of Delos were called *boes* (cattle); the tetradrachms of Athens, *korai* (virgins), alluding to Athene, or *glaukes* (owls); the didrachms of Corinth, *poloi* (colts), from the Pegasus; those of Ægina, *chelonai* (tortoises); the staters of Macedon, *hippotai* (cavaliers); and the darics, *toxotai* (archers). Other pieces were named after the princes who issued them, as, Cræsi, Alexandri, Philippi, Demerateioi, Ptolemaioi, and Bereniceai. The types of the two sides often have a connection with one another, as the head of Apollo with the reverse of a lyre, that of Neptune with a trident, or the head of Hercules with his bow and quiver on the reverse. In many cases, however, no connection can be traced, as on the coins of Tarentum, and the artist selected his subjects from different statues or monuments.

Besides the principal types, various smaller representations, called adjuncts, are introduced upon the field on coins of the third epoch, especially on those of such states as struck a long series. On the coins of Alexander the Great and his successors, these *adjuncts* or mint-marks refer to the cities at which the pieces were struck, as a bee on those of the mint of Ephesus or Aradus, the club of Hercules for Tyre, an anchor for Abydos, a trident for Byzantium. On the contemporaneous coins of cities these *episema* have relation to the eponymous magistrates by whom the coins were issued; and a remarkable instance is the stag on a coin of Athens, the emblem of the great Mithridates with his name, and the elephant of Pyrrhus on coins of Tarentum. Such marks will be found on the currency of Athens, Corinth, the Achæan and Lycian leagues, and on the consular denarii; but they disappear at the time of the Roman empire.

The coins of the earliest period have no inscriptions, the type showing the state from which the coins issued; at first a single letter was introduced, the initial of the name of the city, as A for Argos, Θ for Thebes, Ϙ for Corinth. By degrees these letters became monosyllabic abbreviations of the names of the cities, as ϘPO for Croton, ΠOM for Poseidonia, FA for Elis; dissyllables then appear, as AΘE for Athens, AIFI for Ægina, PECI for Rhegium, and these continued to the latest times. But as the arts developed, the inscriptions become more complete, as HIMEPA (Himera), MEΣΣANION (of the Messenians). These inscriptions generally give the name of the city in the genitive, as ΘΑΣΙΩΝ (of the Thasians); but the nominative sometimes replaces it, as MEΣΣANIOΣ (Messenian), ΣΥΡΑΚΟΣΙΟΙ (Syracusans); and unusual forms are found, as ΣΕΓΕΣΤΑΖΙΒΕΜΙ (I am from Segesta), ΕΡΥΘΕΜΙΣΗ (I am the stamp of Erythræ), ΣΕΥΘΑ ΚΟΜΜΑ (the type of Seuthes). The neuter form is also found, as ΑΡΚΑΔΙΚΟΝ (Arcadian money). These inscriptions follow the style of the epoch, and are written from right to left, or *vice versa*, and boustrophedon. Generally the name or initial of the city is on one side of the coin, occasionally it is repeated on the other; it is inserted to suit the type, at one side, across the area, or all round the hollow square: in some instances it is divided, the first half, as ABA, on one side, and KAINON (Abacænium) on the reverse. In some rare cases it is placed on the type, as AINI (Aenos) on the petasus of Hermes; ΑΡΓΕΙ (Argos) and ΕΛΛΕΙΩΝ (Elis) on the diadem of Hera. Till the fall of Greece into the power of Alexander, the civic legends generally continue very simple; but after that period epithets are used, as ΤΥΡ (ou) ΙΕ (pas) ΑΣΥΛ (λου) (Tyre a sacred Asylum); and under the Romans the states are called by their epithets, as ΑΥΤΟΝΟΜΟΣ (self-governed), ΑΤΕΛΕΙΑ (untaxed), ΕΛΕΥΘΕΡΑ (free), ΜΗΤΡΟΠΟΛΙΣ (metropolitan), ΝΑΥΑΡΧΙΣ (a port), ΑΣΥΛΟΣ (an asylum), ΠΡΩΤΗ (first). Explanations are rarely given, as ΑΛΠΙΣΣΑ ΘΕΣΣΑΛΩΝ (Thessalian Larissa), ΝΙΚΑΙΕΩΝ ΤΩΝ ΚΑΙ ΣΚΥΘΟΠΟΛΙΤΩΝ (of the Nicæans, alias Scythopolites in Samaria). The municipalities out of flattery often adopted Imperial epithets as ΚΛΑΥΔΙΟ-ΣΕΛΕΥΚΕΩΝ (of the Claudian Seleucians), ΤΑΡΣΟΥ ΣΕΥΗΡΙΑΝΗΣ (of the Severian Tarsus), after Claudius I. and Severus. Occasionally the names of rivers are recorded, as ΗΥΨΑΣ (the Hypsas) on coins of Selinus, ΑΡΕΘΟΥΣΑ (the Arethusa) on those of Syracuse; and the names of local deities often accompany the types.

ARTS AND SCI. DIV. VOL. V.

The Demos (or people), Syncletus (or senate), and Boule (or council), appear on late coins. Alliances between the cities are indicated at an early period by the initials of two cities, at a later age by the word ΟΜΟΝΟΙΑ. The participation in games is shown by ΚΟΙΝΟΝ (community).

The names of persons appear first on the archaic coins of the second period, and generally in the genitive, indicating the eponymous magistrates. The earliest names are those of the kings of Macedon, the archons of Abdera, as ΑΛΕΞΑΝΔΡΟΥ, Alexander of Macedon, B.C. 474, and others. The title of king indeed appears with Getas, King of Hedonis, about 474 B.C., but it forms an exception to the rule, the title of king being first assumed by Alexander the Great. His successors adopted titles in addition to their names, and Antiochus XII. is called the King Antiochus, Dionysos, illustrious, father loving, Victorious. Besides the title of king, others appear, as the Ethnarch applied to Herod, and dynastes to Polemo of Olba. A rarer address is that of ΕΠΙ, "under," prefixed to the name of the magistrate, which occurs on the coins of Hicetas of Syracuse, but is commonly used on the imperial Greek coins. The inscriptions of these coins have prefixed to the names of the magistrates the offices which they held in the different cities, as the scribe (γραμματεὺς), archon (άρχων), mayor (εφορός), prætor (στρατηγός), proprætor (αντιστρατηγός), magistrate (πρυτανεύς), treasurer (ταμίης), high priest (ἀρχιερεὺς), priest (ιερεὺς), or priestess (ιερεῖα), president of the games in Asia (Ἀσιαρχός), director of the gymnasium (γυμνασιαρχός), of the festivals (πυργυριαρχός), master of the games (ἀγωναρχός), theologian (θεολόγος). Some coins from the imperial times have inscriptions recording their dedication by individuals or magistrates to a district or city, as Hostilius Marcellus, priest of Antinous, has dedicated it to the Achæans. On the coins of Macedon, after its subjection to Rome, the name of the people is in Greek, ΜΑΚΕΔΟΝΩΝ, that of the magistrates, ΑΕΣΙΛΛΑΣ, in Latin.

Subordinate to the names of princes and magistrates are dates first introduced by the successors of Alexander. The Egyptian coins are dated in the Egyptian regnal year till the time of Diocletian, and are preceded by Λ (λυκάβος), or year; the imperial coins often have dates preceded by ET or ΕΤΟΥΣ, "year"—especially those of the east—the chief æras found are the Seleucian commencing B.C. 312, in Syria, Phœnicia, and Judæa; the Pompeian, B.C. 63, in Syria and Phœnicia; the Cæsarian, B.C. 47 or 48, in Syria; the Actian, B.C. 31, in Syria; the Egyptian, B.C. 300, commencing with Ptolemy I.; and that of Pontus, B.C. 296.

The names of games, as ΚΑΙΣΑΡΕΙΑ, the Cæsarian, ΑΤΤΑΛΕΙΑ, the Attalian; and many others are inscribed on imperial coins.

Inscriptions recording the value are seen on a few rare imperial coins, as ΔΙΑΡΑΧΜΟΝ, a didrachm, on a silver coin of Nero, struck at Cæsarea, in Cappadocia; and on a copper coin of Rhodes, ΔΡΑΧΜΗ, or ΔΡΑΓΜΗ on those of Ephesus; and ΔΡΑΧΜΑ on a bronze coin; ΑΣΣΑΡΙΟΝ, ΔΥΟ, ΤΡΙΑ, ΗΜΙΣ, on the copper of Chios; ΤΡΙΟΒΟΛΟΝ on those of Samothracia; ΗΜΙΟΒΕΛΩΝ on those of Ægium; ΧΑΛΚΟΥΣ on coins of Antioch; ΔΙΧΑΛΚΟΝ on those of Chios.

Single letters besides the names of magistrates and cities, and ligatures of letters called monograms, are of frequent occurrence on the coins.

Sometimes the names of cities are thus compressed, as Π, Parium; X, Achæa; Y, Tyre; or the name of the eponymous magistrates;

dates are rarely thus expressed. On the coins of some cities and princes, solitary letters are used to indicate the order of the issue of the coins from the mint, the letters being used in alphabetical order, and when the series was exhausted the letters were doubled for a new series. The silver coins of Arsinoë have single, and the gold double letters to mark the order of issue.

It has been usual to consider the currency according to the system of Eckhel, or a geographical order from west to east, while the actual chronological sequence is from east to west, the earliest coins being of Asia Minor and the Isles of the Ægean. A still more philosophical arrangement would be that of the coins of each stage of the currency. The coins of Britain and Spain are imitated or derived from the coins of Philip II. of Macedon, or Hiero II. of Sicily; the types of the copper are rude portraits of Greek gods, and symbols, as grapes on the coins of Acinippo, alluding to the name of the cities. The gold and silver are copied from the Roman aurei and denarii of the Consular period, and of a similar standard and type as the Dioscuri; even the copper have the uncial globules which mark the subdivision of the *as*. Their legends are in the Celtiberian characters, derived from the Greek and Phœnician, and they are supposed by some to have been issued as early as B.C. 200, by others as late as B.C. 84-74, the date of the insurrection of Sertorius, and named the Oscense argentum, from Osca, his capital. (Livy, xxxiv. 10, 41, xli. 43. De Saulcy, 'Monnaies Autonomes de l'Espagne,' 8vo, Metz, 1840; Gailliard, 'Description des Monnaies Espagnols,' 4to, Madr., 1852.)

The coins of Gaul are divisible into three periods. 1. Earliest imitating the staters of Philip II. & III. after the conquest of Macedon, B.C. 278. 2. Those with Latin legends apparently from B.C. 100-21. 3. Those with the names of cities and chiefs on each side, the inscriptions either in Greek or Latin, or both mixed. These last two classes imitate the Consular silver, but with great provincial variety. Besides

the Celtic coins are the earlier coins of Massilia or Marseilles, Glanum, with the type of a female head and lion of elegant workmanship, and belonging to the Greek series, consisting of the drachm and its subdivisions. The Gaulish series contains staters, of drachms of silver, and potin of 6 copper, 2 lead, 1 tin, or copper of small size to imitate *lepta*, and the first are cast. Besides these are bronze coins of two colonies, Nemausus or Nîmes, founded with veterans from the Egyptian campaigns, and having on the obverse the heads of Agrippa and Augustus, and on the reverse a crocodile bound to a palm tree, and Lugdunum or Lyons, with the head of victory and a lion. The earliest British coins, like those of the Gauls, are imitations of Philippi, and are followed by those of chiefs and kings of A.D. 100, the most remarkable of whom are Cynobelin, Tasciovanus, Dubnovellaunus. They are in all metals, of small size, on the Greek standard, and exhibit great local differences: two cities are named on these coins, Verulamium and Camalodunum.

Following the western arrangement, the next coins are those of Italy and Sicily. I. The Greek series is remarkable for its number, the beauty of its art, and the interest of its types. The art is of a softer and more florid character than that of Greece Proper, and there are no coins so old as those with incuse squares of the older Greek style, but instead a remarkable kind having the type in relief on one side, and incuse on the other, like bracteats or embossings on paper. All these Greek coins are struck in Southern Italy or Magna Græcia. The oldest coins are of Sybaris, destroyed B.C. 510; drachms and demi-drachms with a bull; of Poseidonia, subsequently Paestum, B.C. 453-448 with Poseidon; Croton, founded by Achæans, B.C. 710, with the tripod of Apollo taken by Hercules from Delphi, Hercules and Apollo destroying Python; of Metapontum, B.C. 700, with the golden summer or ear of corn surmounted by a grasshopper, Apollo and Artemis; and of Caulonia with Apollo; of Laos, with an ox; and of Termesa with armour. Of the best period of art are the beautiful coins of Thurium, with the helmeted head of Athene, with Scylla and the butting bull, those of Locri with the shade Ajax Oileus, Rome and Faith; of Rhegium with the horse and mules of Anaxilaus, of Velia with the helmeted head of Athene, and a lion; of the Brettii, with Neptune and Venus of fine art. Still more remarkable are those of Tarentum, with Taras and Phalanthus, and the young Taras running to his father Neptune; Heraclea its colony, B.C. 443, has the head of the Lacinian Juno and Hercules, Cumæ, Glaucus, Scylla, Cerberus alluding to the Sibyl, and crabs; Neapolis and Nola, the head of Parthenope and Dionysus Hebon; Hyria has Minerva and Juno; Terina the goddess Pandeina or Iris drawing the water of the Styx; Arpi, Ceres and a horse. Many of the coins show the state of political events, elephants indicating Pyrrhus and Hannibal at Tarentum and Cumæ, and the head of Janus, the progress of the Roman power.

II. Coins inscribed in the languages of the people of Italy. The principal of these are the Oscan coins of Capua, Atella, Teate, and those issued by the confederated chiefs in the time of the Social and Marsic wars, imitating the Roman denarii in weight and type, but of much ruder character and workmanship; one of these has the word *Safinim* or Sabinorum in the Oscan dialect.

III. Coins with Etruscan inscriptions consisting of one or two gold of uncertain authenticity, a few silver, and a large series of the As Grave and its divisions issued by Cortona, Volaterra, Tuder, Iguvium Vestini, Hadria, Firmum and Ariminum, the last with the head of the victorious Gauls.

The other ases have various types for each state and series, but the wheel is a normal type, besides which are other unascertained series of Etruscan states.

The coins of Sicily are as fine as those of the Peninsula, but none belong to the first period of art with hollow square. The island is remarkably rich in silver coins. The tetradrachms of Agrigentum have the river, the sea eagle, and the crab; the tetradrachms and didrachms of Camarina, Hercules, Athene, and the Hipparis; the tetradrachms of Catana have chariots; those of Gelas the river as a human-headed bull, or as a horned youth; the didrachms of Himera, the cock sacred to Æsculapius, and the river. The tetradrachms of Leontini have the lion's head, the celebrated corn of its plains and chariots; the drachms of Messina, the curved port, and the types of its Samian colonists, a lion and bull, the horses, mules, and chariots of Anaxilaus, as the Mamertini Mars; Naxos has beautiful tetradrachms with a couchant Satyr; the tetradrachms of Segesta the Crimisis, and the nymph Segesta; the tetradrachms of Selinus, Apollo and Artemis Epicurioi and the Hypsas sacrificing. Syracuse has many types, but they principally are chariots, referring to the reputation of Sicilian horses, to obtain which Alcibiades is said to have projected the unfortunate expedition of the Athenians. The earliest dated coin, the dekadrachm or Demarateion, B.C. 479, has the head of the Arethusa surrounded by dolphins, a biga and the lion of Gelo I.; the later tetradrachms supposed to be struck under Dionysius I., B.C. 368, have the same head in a less archaic style, a quadriga with a panoply of armour, and the word *athla* prizes. The gold pieces are also fine, and the currency of the princes commencing with Agathocles, and ending with Gelo II., and comprising the queen Philistis, only known from her name on the seats of the theatre, is remarkable for the beauty of work and art embellishing their portraits. Besides the Greek coins there are tetradrachms with Carthaginian

legends struck in Sicily, and others of finer work attributed to the second Dionysius.

The islands near Sicily have Phœnician deities and legends, and principally copper coins. In the Crimea or Tauric Chersonesus, the normal type is the head of Panticapæum. Istrus, the Medusa's head reflected. In Thrace the didrachms of Abdera have the gryphon; those of Aenos of remarkable beauty, the head of Hermes and the wine-press. Byzantium, which is said to have issued iron money, has the bull, and the head of its founder, Byzas. Maronea, has a series of fine tetradrachms with the horse of Poseidon and the vine of Dionysos, alluding to its wines. Thasos has triobols with the head of Dionysos, and an amphora. The regal series is rich in didrachms of Seuthes I., with a horseman and remarkable inscriptions, and with the copper of Seuthes III. A beautiful suite of coins is those of Lysimachus, whose staters imitate Alexanders, and whose tetradrachms struck all in Asia and Europe, like the series of Alexander, as at Ephesus, Methymna, Tomi, and Byzantium, have on one side the head of Alexander with the ram's horn, as son of Ammon, and on the other Pallas Athene Nicephoros seated. At Chalcedon, in Bithynia, the tetradrachms give the veiled head of his consort Arsinoë. There is also a remarkable tetradrachm of Mostis struck by Sadalus in the 47th year of his reign, with a portrait.

In the neighbouring state of Macedonia, the tetradrachms of the province struck in the first division, at Thessalonica, have the head of Alexander, the club of Hercules, and the name of the questor Æsillas; the second and fourth divisions are found, but not the third; the didrachms of Acanthus have a lion devouring a bull, and are of the second period. Aeneia has the head of Æneas; the beautiful tetradrachms of Amphipolis, the laureat head of Apollo, and the torch of the lampadophoria; those of Chalcidice, the head of Apollo and his lyre; the archaic ones of Lete, a satyr and nymph; Neapolis, a Gorgoneion; of Philippi the ancient Cranides, there are staters with the head of Hercules, and the Delphic tripod.

Of the princes of Pæonia, commencing with Audoleon, B.C. 340-330, there are fine didrachms with a helmeted head and horse; those of Eupolemos, Lyceius, and Patraus, have a horseman overthrowing an enemy. The regal series of Macedon are remarkable for the light they throw on the history of the coinage. The coins of Getas, king of the Hedones, represent a man and two oxen; those of his contemporary, Alexander I., a man and horse; a very archaic dekadrachm has a man in a car drawn by a bull; and in the area the helmet of Caranus. There are drachms, didrachms, and obols of Archelaus, bronze coins of Æropus, didrachms of Pausanias and Amyntas II.; drachms and brass coins of Perdiccas III.; the goat refers to those which accompanied Caranus to Ægæ. The staters of Philip II., coined from the gold of Mount Pangæum, have the head of Apollo alluding to Philip's protection of Delphi, and a two-horse chariot, alluding to his victories in the Olympian games; the silver currency, principally didrachms, have the head of Zeus and a rider. Of Alexander the Great there is a great series of two or three issues; this monarch recoined the whole currency of his empire, and struck numerous double staters with the head of Pallas and Victory, and tetradrachms with the head of Hercules and Zeus Olympius, in copper in the principal cities, suppressing the local mints; the places of mintage are distinguished by the symbols of the coins of the cities where minted, placed in the area with the initials or monogram of the name of the city, as the Rose for Rhodes, the head of Chnephis for Alexandria, the bee for Ephesus, the lion and bull for Miletus. The names are given in contraction or by monograms as MTPI Myrina, KOAO for Colophon.

Philip III., has staters and its subdivisions, tetradrachms on the type of Alexander the Great, and is distinguished from his predecessors by the assumption of the title of King. Cassander, struck only brass, with the head of Hercules and a lion. Philip IV. and Alexander IV. only drachms and small coins; Antigonos, staters with the head of Pallas and a trident, fine tetradrachms with the head of Dionysos, and Apollo seated on a ship, referring to the victory of Cyprus, B.C. 306; Demetrius I., staters on the type of Alexander, tetradrachms with his portrait, and Poseidon; others with Poseidon Promachos, and Victory sounding a trumpet on a galley, for the victory at Cyprus. Antigonos Gonatas, has tetradrachms, convex, like the silver shields of the Argyraspides with the head of Pan, and Pallas hurling thunder, on his copper Pan erects a trophy. Passing to Philip V., there are fine tetradrachms on the type of Antigonos, with the head of Perseus and the club, or his portrait, and Pallas hurling thunder, besides didrachms, drachms, and copper. Of the unhappy Perseus, B.C. 168, there are fine tetradrachms with his head, and the eagle and thunderbolt by the artist Zoilus. Of Philip VI., there are only copper.

Thessaly abounds in silver coins, the principal type is the horse, the drachms have the head of Zeus crowned with oak, and the Pallas Itonia, the eight obol pieces of the Aenianes, the head of Pallas and the hero Phenicus slinging, the triobols of Lamia, the ivy crowned head of Dionysos, and a diota, or a tripod in a square, the drachmæ of Larissa have Jason and the bull of Colchis, the horse in a square, the sandal of Jason left at the Anapus, the head of the hero Aleuas and the eagle and thunderbolt; the didrachm, the head of Larissa or Coronis and a horse; those of the Octaei Hercules and a lion or spear; the drachmæ of Phalanna a youthful head and horse; those of Phææ

a female drawing water from a fountain; of this town are the tetradrachms of the tyrant Alexander, B.C. 363-359, with the head of Larissa or Coronis and a horseman. The early tetradrachms of the Oreskii have a horseman with horses and spears. The coins of Illyricum are not interesting; the drachms of Apollonia have dancing nymphs and a volcano. Of Epirus there are tetrobols with the heads of Zeus and Hera and a thunderbolt in an oak crown. The most important coins are those of the monarchy—of Neoptolemus and Alexander, B.C. 362-322, there are only brass; but of Alexander I., B.C. 342-332, there are staters of fine work with the head of Zeus and a horseman, and silver obols with Helios; those of Pyrrhus, B.C. 294-272, are of great beauty, and consist of hemistaters with the head of Artemis and Pallas-Athene and the same, and crown; staters with the head of Proserpine and Athene-Promachos struck in Sicily; Dyrrhacium has early coins like Coreyra and drachms with the head of Dionysos and a Pegasus of Corinth; the didrachms of Anactorium have the head of Pallas and Pegasus; the didrachm of Leucas has Artemis Nauplia with a ship and hind; Thyreum, Achelous and Apollo; Aetolia the Achelous and Atalanta amidst shields, and triobols with the head of Atalanta and the boar of Calydon. The didrachms and hemidrachm of Locris offer the head of Persephone and Ajax Oileus, the old drachms and triobols of Phocis the bucranium suspended on the temple and the head of Apollo. The archaic didrachms of Thebes and Boeotia have the celebrated bucklers; the later didrachms the head of Dionysos, his golden amphora, and Poseidon, Hercules strangling the serpents, or shooting an arrow, a rare tetradrachm, the head of Zeus and Poseidon.

The coins of Athens have been already described; the lepta of Eleusis have Demeter in a biga of winged serpents and a sow; those of Megara, the head of Apollo and his lyre. Of Achæa there is a remarkable series of the league, with the head of Zeus and the monogram of Achæa and the initials of the towns; others have Zeus Nicephorus, and the didrachms of Corinth have the Φ for the initial of the Demeter. The didrachms of Corinth have the Φ for the initial of the Demeter. The didrachms of Pallas Chalinitis in the Corinthian helmet, name of the city, the head of Pallas Chalinitis in the Corinthian helmet, and Pegasus, or Bellerophon and the Chimera; on the imperial are Ino, Melicerte. The drachms of Patrae resemble those of the Achæan league; those of Phlius have a wheel. The archaic drachms of Sicyon have a flying dove, with $\Sigma\epsilon$, the archaic initial of the city, of great beauty; the later, a Chimæra, with the same bird, and are of great beauty. The archaic didrachms of Elis have an eagle with a serpent, emblem of Olympian Jove, and FA for Falis, the Æolic name of the city, with a thunderbolt; later coins, the eagles feeding off hares, and a winged Victory seated; and the last, a copy of the head of the celebrated Hera of Polycleitus, with her name Hera inscribed upon the kredemnon or attire. The drachms of the Crani in Cephallenia have the ram of Helle; Zacynthus has the head and tripod of Apollo; Ithaca, Ulysses.

The Messenian didrachms have the head of Demeter or Persephone bound with ears of wheat, and on the reverse Zeus Ithomatas; the drachms of Laconia, the head of Hercules; and the tetradrachms of Cleomenes the portrait of this monarch and the armed Aphrodite, and on late copper Lycurgus himself. The drachms of Argos, a wolf; in a smaller piece the protome of a wolf, and on the reverse A in a square, the head of Hera, and Diomed; Træzene has the trident of Neptune. Those of Arcadia have Zeus Lycaeus with an eagle, and a female head in a square; the silver coins, the head of Pan; the hemidrachms of Heræa, the head of Hera; Mantinea, the bear and acorn; those of Megalopolis, the laurelled head of Zeus Lycaeus, and Pan seated holding a pædum, and an eagle on Mount Lyceus; Pheneus, the heads of Proserpine and Meleager; Stympthalus, the head of Artemis, and Hercules and the Stympthalian birds. In Crete the art of the coins is peculiar, rather coarse, and the pieces are often large. The drachms of Aptera have the head of Zeus or Hera, and Hermes or Apollo and Aptera; those of Gnosus, the Minotaur holding in each hand a bull, and the labyrinth; the didrachms, the head of Minos, Hera or Ariadne; those of Cydonia, the ivy-crowned head of Dionysus, and Cydon with his hound, holding a bow; the tetradrachms, Artemis, with a hound and torch. The drachms of Elyrus have a bee of the celebrated hives which nourished the Cretan Zeus, and the celebrated goats which by eating the herb dictamnus drew the iron from their wounds; the old didrachm of Gortyna, Europa seated in the tree, with Zeus as an eagle, and Zeus under the form of the bull; Hierapytna, a palm tree and eagle; the didrachms of Itanus, Tritons and two sea serpents; the very old drachms of Lyttus, a flying eagle and the forepart of a boar; the didrachms of Phæstus, Hercules killing the hydra, bulls and ear of corn, and an ox bound and feeding, or the winged Talos hurling stones at all who approached the island, and Zeus Gelchanos seated on a tree holding a cock. Polyrrenium, Priansus, and Rhæucus have interesting coins. Eubœa has Aphrodite; the tetradrachms of Carystus, a cock, and a calf sucking a cow. The didrachms of Chalcis, Apollo and a lyre; the triobols of Histia, the head of Hera, and the prow of a ship; the tetradrachms of Eretria, the head of Artemis Amarynthia, and a bull with a fillet on his horns. The old didrachms of Ceos, a bunch of grapes and incuse square; the didrachms of Melos, a pomegranate. Ceos has a pomegranate; Coresia a sepia, the copper of Julis, the head of Aristæus, and a bee; the didrachms of Paros, mentioned by Hesychius, have the head of Ariadne and a goat; Tenos has the head of Dionysus, with the ram's horn and grapes.

The Asiatic coins commence with the Cimmerian Bosphorus, which extend from B.C. 289 to A.D. 337. The first of them, those of Parisades, staters, resemble those of Lysimachus. The tetradrachms of Mithridates III., B.C. 297-266, are of fine although barbaric work, with a good portrait. Those of the great Mithridates IV., B.C. 123-62, both the staters and tetradrachms, give fine portraits of the king. Those of Pharnaces II., B.C. 62-47, are nearly as fine. The later kings, commencing with Asander, B.C. 46-13, struck a series of gold and electrum staters, didrachms of base alloy, and copper, with portraits of the Cæsar as their reverses and dates. Those of Pontus are not remarkable. Amastris has the head of Amastris the Amazon, its founder. The tetrobols of Cromna have the heads of Zeus and Hera; the drachms of Sinope with Greek or Phœnician inscriptions, have the head of the local eponymous nymph and an eagle devouring a tunny. The brass obols, Perseus and the Ægis. In Bithynia, the old drachms of Chalcedon have a bull and incuse square; the drachms and trihemio-bols of Heraclea, the heads of Hercules and Hera; the drachms of Cius, the head of Apollo and a ship; the didrachms of Heraclea, Heracles and the city, and didrachms of the tyrants Timotheus and Dionysius. There is a fine regal series of tetradrachms and copper of the kings of this state, with portraits, as Nicomedes I., B.C. 276-250, Prusias II., B.C. 149, with his head winged as Perseus and Jupiter; and of Nicomedes II. These coins are dated with the Bithynian era.

In the neighbouring state of Mysia, the most remarkable autonomous coins are those of the celebrated electrum and gold stater system of Cyzicus, already mentioned, and tetradrachms with the head of Proserpine and a lion's head. Of Lampsacus, there are staters with the head of Poseidon, the bust of Demeter, and hippocampus; the didrachms have Hercules. Of Parium, there are staters with the head of Demeter, and drachms with a goat. The most remarkable of the coins of Pergamus are the cistophori, or tetradrachms, with a snake escaping from a basket, all in an ivy crown, or two snakes entwined round a bow. A fine series of tetradrachms of the kings of Pergamus commence with Philetærus, B.C. 288, Attalus I., B.C. 241-147, Eumenes II., B.C. 197-159, Aristonicus, with their portraits, and Pallas Athene. Of the Troas, the drachms have the Gorgonium, and an anchor or eagle, and Trojan myths.

The coins of Abydos have the head of Pallas, Artemis, and the Gorgonium, an anchor or eagle; of Alexandria Troas, the head of Apollo Smintheus, and a pasturing horse; the tetradrachms of Tenedos, described by Aristotle and Suidas, have a double head and the bipennis with which Tenes cut the fatal rope. The drachms of Aegæ in Aeolis present the head of Apollo and Zeus Aetophoros and a goat; the tetradrachms of Cyme the head of the eponymous Amazon, a horse, and jug; those of Myrrhina, the head of the Grynæan Apollo, a female offering, and a diota. The island of Lesbos struck for itself only bronze coins, but the drachms of Methymna have the head of Pallas and a bull, of fine work and old style; Mytilene the head of Apollo and a lyre; Clazomenæ has beautiful staters with the head of Apollo and a winged boar, and didrachms with the same head and a swan; of Ephesus there are staters with the head of Artemis and the Ephesian Artemis; cistophori, tetradrachms with a bee, deer, and a palm-tree. Erythræ has a stater with a stag; the tetradrachms of Magnesia have the head of Artemis and Apollo on the Mæander, the didrachms, a rider and bull; one has the name of Themistocles, then its dynast. Miletus offers coins of the oldest style with the laurelled head of Apollo, a lion, and star; Phocæa has staters and silver coins with a seal; Smyrna, a double stater, with head of Cybele, and a female; bronze coins with Homer; and sesterces struck by the prætor Theudianos. Teos has silver didrachms with a gryphon, and brass coins with Anacreon. The type of Chios in gold and silver is a sphinx and diota. Samos has the head of Apollo and a Pegasus. Of Cnidus Antiochia, of Caria, has the head of Apollo and a Pegasus. Of Cnidus there are coins of great antiquity, with the heads of Aphrodite and a lion; Myndus, Serapis and his head-dress; Nysa, the rape of Proserpine; Termeros has a trihemio-bol of Tymnus its tyrant. Of the Carian princes, commencing with Hecatomnus, B.C. 381, and ending with Pixodarus, 336, there is a fine series of tetradrachms, didrachms, and drachms, the normal type of which is Zeus Labrandenos. The didrachms of Calymna have the head of Mars and a lyre. Of Cos, there are silver coins with Hercules and crabs, and tetradrachms with the dance of Apollo before the tripod, while the brass coins have Aesculapius. The gold and silver coins of Rhodes have the head of the Colossos and the rose.

The coins of Lycia consist of an early series of didrachms, drachms, and trihemio-bols, of the earliest Attic standard, with incuse squares with symbols, the types of the oldest B.C. 600; the normal type is a ring with three or four hooks. These early coins have inscriptions in the Lycian characters, and the names of Tlos, the Troes, Pinara, and other cities, are found on them. A later series of didrachms, having on one side the head of Pallas armed, and on the other the head of a satrap, and inscribed Ddenenefele, Pttarazi, Feggere, Arina, and Garue, probably record the names of satraps after the Persian conquest. (Sir C. Fellows, 'Coins of Lycia,' 4to, London, 1855.) Of Lycia there are also a series of drachms struck by the Lycian league, with the head of Apollo and lyre, and the initial letters of the states.

In Pamphylia, and Aspendus, the didrachm has wrestlers, three legs,

and a barbaric legend; Perga didrachms of the post-Alexandrine epoch, with Artemis Pergaia; Side, a series of fine tetradrachms, with the head of Athene, Victory, and the pomegranate, the name and emblem of the city. The states in Pisidia are numerous: the coins of Selge with slingers, and Andeda are the most interesting. The bronze coins of Iconium have the eikon or portrait of Perseus. In Cilicia, Celenderis has didrachms with a kneeling goat looking behind, and a horse; Nagidus, Dionysos; Mallus, an Asiatic deity, Hermes and Herse. Olba brass coins with the portraits of the priest, princes, Polemo, and Ajax. Soli didrachms with a head of Pallas, and bunch of grapes. Pompeiopolis, the heads of Pompey and Aratus. The didrachms and tetradrachms of Tarsus have Tyche, or Fortune, Zeus, a lion, a lion devouring a bull, and the kings Tarcondimotus, and Philopator I., in B.C. 100-1.

The most remarkable coins of Cyprus are the gold and silver with the heads of Zeus and Aphrodite commenced by Evagoras, B.C. 380, and continued by his successors. Those of Amathus with a ram, and Soli with Astarte. In Lydia, the principal coins are cistophori, of Sardis and Tralles, and numerous imperial coins. Phrygia is chiefly remarkable for the cistophori of Apamea, Laodicea, and a series of imperial coins. Of Galatia there are bronze coins of some towns of imperial times, and of the kings, Dejotarus, the friend of Cicero, and Amyntas, B.C. 36-25. Cappadocia is chiefly remarkable for the imperial mints at Cæsarea, which struck in all three metals, with the portraits of the emperors and the mountain Argæus; and the tetradrachms, didrachms, and drachms of the kings Ariarathes and Ariobarzanes, B.C. 220-17. The coins of a few kings and Tigranes are the only ones that can be referred to Armenia. Of the Syrian kings there is a long series in all metals, but chiefly tetradrachms, commencing with Seleucus I., B.C. 312, and terminating with Antiochus XIII., B.C. 60. These have generally on one side the head of the monarch bound with a diadem, and on the other Apollo on the cortina. The most remarkable are the tetradrachms of Seleucus I., representing him in a triumphal car drawn by elephants; the staters and tetradrachms of Tryphon having on the reverse a helmet with a horn; the unique coins of Cleopatra, mother of Antiochus VIII.; those of Antiochus VIII., with the reverse of the tomb of Sardanapalus at Tarsus. All these coins have indications of the cities where they were struck; they are of great beauty but difficult to assign to the proper princes. There is a coin of Iotape of Commagene with her head and scorpion, struck B.C. 70-40. Of "Antioch the Great" there are autonomous bronze coins, with Zeus, the tripod, and the Pompeian æra; then the imperial coins, with the celebrated statue of the city on the reverse, and autonomous coins with the Actian æra, with a lyre, ram, and sun and moon; finally, imperial tetradrachms with the Cæsarian and Actian æras, from Galba to Volusian, and copper of the Roman colony with S.C. on the reverse, from Antoninus Pius to Valerian. The coins of Apamea have an elephant, but of Laodicea there is a tetradrachm with the head of the eponymous Amazon, and Zeus Nicephoros. Of Damascus there are both autonomous and imperial coins; some of King Aretas, with the head of Cybele, or Dionysus, and a deer. Berytus has silver with the same head and a deer. Sidon has tetradrachms with the portraits of Antiochus IV., a ship, and Astarte, and bilingual copper. Tyre has coins with the head of the Seleucids, from Antiochus IV. to VIII., the eagle, or the Tyrian Hercules. Aradus, tetradrachms, with the head of the city and a Victory.

The coins of Judæa do not date earlier than Simon Maccabæus, B.C. 144-135, who issued shekels of silver with the manna pot, and Aaron's rod, the beautiful gate of the temple, and inscribed in Samaritan characters, with 'Jerusalem the Holy,' and 'the shekel' or 'half-shekel of Israel,' and the year of his reign, or the 'liberation of Israel.' The subsequent monarchs, such as Herod Antipas, B.C. 4-39 A.D., and Herod the Great, and Agrippa II., issued copper lepta, the widow's mites, the Romans having taken away the right of coining silver. The coins of Arabia, Mesopotamia, and of the kings of Edessa have little interest. Those of Timarchus, king of Babylon, B.C. 164-62, are rare.

The series of Parthian coins consists of tetradrachms, drachms, oboli, and copper coins; the drachms commence with Arsaces II., B.C. 253, and terminate with Vologeses V., A.D. 227, their maximum weight is 54 grs. Their normal type, the head of the monarch in a tiara with the Scythian Apollo. The tetradrachms commence with Arsaces VI., or Phraates I., B.C. 181, and continue in their series, their maximum weight is 222 grs., their types are rather more diversified, having the king seated, Victory, Hercules, Fortune. The brass coins commence with Arsaces III., or Artabanus, B.C. 216. Their types are still more varied. These coins have on them the date of the year, and the name of the month in which they were struck. In Persia, the early Achemenidæ struck both the gold and darics. The later Sassanidæ struck a series of coin of flat character, having on one side their bust in oriental attire, and on the reverse a fire altar, at first accompanied with Greek, and afterwards with Pehlvi inscriptions, commencing with Artaxerxes I., A.D. 223, and ending with Chosroes I., A.D. 579. Bactria, the present Cabul, has coins of a dynasty of princes unknown to history, commencing with tetradrachms of Diodotus I., B.C. 250, and Euthydemus, B.C. 245, Eucratides, B.C. 180, and continuing till Mayes, B.C. 95. The coins of these princes are struck on the Greek standard

and model, and have allegorical legends with Bactrian inscriptions. These coins are succeeded by those of Parthian princes, commencing with Azes and Mayes, of square shape, principally didrachms, and with Arian legends, and end with the Indo Scythic gold coins of Kadphises, B.C. 85, and Kanerki, A.D. 40, with a figure of the monarch, the god Mithras, and the bull Nandi. Of the characene there are only the coins of the monarch Monoeses.

A series of coins with Phœnician inscriptions, were struck by the Satraps of Persia in Syria, Phœnicia, and Asia Minor, Palestine, and Cyprus, besides which, the kings of Phœnicia and Gebal struck coins with Greek types and Phœnician inscriptions (De Luynes, 'Numismat. des Satrap,' 4to., Paris).

The coins of Egypt are a remarkable series, commencing with the Aryandics. The Lagidæ have a long series of fine didrachms, tetradrachms, drachms, and staters, and tetrastaters, and pentadrachms. The normal type is the head of the monarch on one side, and on the other, an eagle or cornucopia, with the name, sometimes titles of the monarch, adjuncts and monograms of the cities of Syria, Cyprus, and Egypt, in which they were struck. Great difficulty is however felt about the assignment of many of the coins. The most remarkable pieces are the gold of Soter, with Alexander's body transported in a quadriga of elephants, those with the heads of Soter and Berenice on one side, and Philadelphus and Arsinoë on the other, the large gold and silver series of Arsinoë. There are only copper and silver of Cleopatra and Antony. The brass currency, apparently adjusted to the brass talent, has remarkably large pieces, and submultiples of small size, generally with the head of Jupiter Ammon and one or more eagles. The coins of the Ptolemies are well executed, and of great beauty and interest.

The Romans adopted, on their conquest, the system of the Ptolemies, and the use of the Greek language, striking didrachms of a base silver, with the head of the emperor accompanied by his titles on one side, and on the other allegorical figures copied from the Roman coins, with the date of the year in which they were struck, offering an important series for the chronology of Rome. These didrachms commenced under Tiberius and Nero, and continued till the Antonines; more alloy was used under Marcus Aurelius and Commodus. From Septimius Severus to Gallienus mere potin was employed, and the didrachms give place to the last, and become rare after Gallienus. From Aurelius to Diocletian only copper of small size but thick were in use. After the revolt of Firmus, A.D. 272, the mint was left at Alexandria, and continued till the close of the Lower Empire, but Latin legends were introduced on the coins A.D. 296. The copper coins are the large brass, or tetradrachms, of about 290 grs., the second brass, or didrachm, of 136 grs., the drachm of about 63 grs., adopted on the standard of the Roman brass. The coins of the nomes commence the 12th year of Trajan, and end the 8th of Antoninus; they have the legends, deities and sacred animals of the nomes.

The other coins of Africa are those of the state of Cyrene, consisting of early of the time of the Battiadæ, of the republic, of the Lagidæ, and of the Pentapolis, B.C. 96. The gold tetrastaters, staters, and hemistaters have the head of Jupiter Ammon and the Silphium, or Assafoetida, sometimes with the gerboa on the stalk; the tetrobols with a rider and the Silphium are very fine; the silver currency with like types is also fine. Of the revolted Magas, B.C. 256, there are only bronze coins, with his portrait, and of Ptolemæus Apion, B.C. 96, silver and brass. The states of Leptis, Sabratha, Byzacene, and Zeugitana, offer little numismatic interest, and of Carthage itself there are no coins, although a fine series of Carthaginian coins was struck in Panormus. Hippo Libera and Utica have coins with the supposed heads of Libya and Julia Augusta. Certain coins with Punic legends have been assigned to Mauritanian princes, Masinissa, Micipsa, Jugurtha, and Hiempsal II., and of these are drachmæ with portraits and Latin legends of Juba I., II., Ptolemy, and Cleopatra.

The imperial series struck in the Greek cities under the Roman empire has considerable points of interest, showing the state of the arts, the nature of the magistracies, the titles assumed by the cities, occasionally as still enjoying their municipal freedom. They placed on their coins the heads of the personified *Demos*, or People; *Synkletos* or Senate; *Gerousia*, or Comitia; and *Boule*, or Town Council; but generally from civic adulation the court of the imperial family appear on the coins. The reverses resemble the Roman, but present great variety of type, and are executed with less taste. Their inscriptions are remarkably copious. Their monetary system assimilated itself to the Roman by issuing large brass obols, and medium and smaller sizes to imitate the Roman bronze currency, but the pieces are generally flatter, and the relief lower, and the weight less. The coins of the few Roman colonies have been alluded to, and fall into this system; they struck *permissu Augusti* or *Proconsulis*, by the permission of Augustus or the Proconsul, but were soon suppressed, or converted into imperial mints.

From the coins of the Greeks the natural transition is to the currency of Rome, from which the present monetary systems of Europe have been derived.

Although little has been recorded about the condition of the Greek mints, rather more is known of the Roman. The asses were originally cast, *flavissæ*, but towards the close of the republic were struck; the dies are supposed to have been of hardened brass, the blanks were cast, and then cut or separated at the gate of the mould,

they were then placed with the forceps on the anvil, and struck between the dies by the hammer; occasionally a coin, not having been withdrawn, the next piece was *impressed* with the incuse or intaglio-type, which as it is the obverse, shows that the obverse die was uppermost. The mint itself was held in the temple of JUNO MONETA, or "the Adviser," and the following officers presided over it,—the quaestors, the triumviri monetales, or triumvirs of the money, to whom Julius Caesar added a fourth, and who appear B.C. 289, the director, *optio*; assayer, *exactor*; caster, *flator*, *flatorius*; the placer or feeder, *suppostor*; the striker, *malleator*; and the engraver, *sculptor*; the *offinator*, workman, and *nummularius*, treasurer, and *coenarius*, purifier. They formed a corporation; under the republic the workmen were public slaves, but Caesar appointed freedmen, and the Gothic kings of Rome elevated the social position of the mint masters. The triumviri monetales presided over the issues of all three metals, but the brass continued under the empire to be struck by decree of the senate, while the emperors alone had the right of coining gold and silver, and had their money separate in the treasury (Dio. liii.), which was superintended by the Praefectus Aerarii, or the Procurator in the later times of the empire. In Rome itself the whole establishment was under the Praefectus urbis, in the provinces under the Praesides, and under the barbarian kings of Rome under the mayor of the palace. Bronze dies of the empire have been found.

At the earlier times the Romans had no gold coins, but used the Philippei, or Macedonian stater, a term retained under the later empire ('Lactantius,' i. c. 6; A.U.C. 546), the gold *aurei* were first issued sixty-two years after the denarii. The earliest aurei are supposed to have been coined B.C. 207, and some writers have supposed that originally 48 were struck from the pound of gold till 134 B.C.; 45 from B.C. 134-119; 42, B.C. 119-104; 40, B.C. 104-37; 41, B.C. 37-14 A.D.; 40 under the early emperors till Nero's reign, who issued 45; 50 under Caracalla, 60 under Diocletian, and 72 under Constantine. The aureus was called like the silver coin *denarius*, but weighed 2 scriptulae, or double the weight, and was worth 25 silver coins, and 100 sesterces or large brass pieces called nummi, with some fluctuations. The half aureus or Roman half sovereign was called quinarius at a later period. This was for greater public convenience, the taxes under the empire being paid in gold into the treasury; and under the Byzantine emperor, Alexander Comnenus, the payments of the state issued in copper. The right of striking gold as well as silver belonged to the emperor alone, and it was an act of treason for a subject to place his image on the coin, or even to show the least dishonour to the imperial portrait or effigy, which was considered inviolable. The types of the earliest gold and electrum coins of the Romans, struck in Capua about B.C. 210-180, have on the obverse the head of Mars, or Janus, and on the reverse Roman deities. They are marked behind the head with their value in sesterces, the piece of XX sesterces weighed a Roman scriptula, or scruple, 18.06 grs.; that of XXX sesterces; of XXXX sesterces; and $\frac{1}{2}$ X (lx) sesterces, in proportion. Pieces struck by Sylla and Lucullus, called Lucullians, weighed 10 scriptulae, or 165 grains. Pieces of larger size and heavier weight than the aureus are called medallions, and are supposed to have been issued as medals for the legions. Elagabalus is said to have struck denarii of double, treble, four, and a hundred times the usual size, and even to the weight of two pounds, but such vagaries were destroyed after his downfall. Alexander Severus struck halves called semisses, and thirds, tremisses, to accommodate the remission of taxation to one-third. After the time of Constantine the gold coin was called *solidus*, and *victoriatas*, from the recurrence of the figure of Victory on the reverse. Towards the close of the republic, the aureus was sometimes of electrum, or $\frac{1}{2}$ silver, and under the Lower Empire of obryzum, or gold mixed with copper or rouge. It was generally very pure; at the time of Vespasian, its purity had $\frac{1}{88}$ only of alloy. The proportion of gold to silver was as 1 to 10; B.C. 189, 1 to 9; B.C. 54, under the Empire, as 1 to 12; and as 1 to 14 or 18 from Constantine to Justinian.

The original aurei were 130.1 grs.; under Pompey the highest reach 128.2 grs.; under Augustus they sink to 121.26 grs.; those of Nero have 115.39 grs., and they continued at the same weight under the Empire. Constantine struck 72 to the lb., each weighing 68.5 grs.; these were worth 12 silver miliarenses, and were divided into semisses, tremisses, and quadrantes.

After the victory of Livius Salinator over Asdrubal, A.V.C. 545=B.C. 209, the Romans issued silver coins weighing about 62 grains, on the model of the attic drachmae. These coins were called *denarii*, or pieces of ten asses; *argentei*, silvers; *bigati*, having a two-horse chariot or *quadrigati* with four. They are about the size of a sixpence, but thicker, and are the Roman *Franc*. Foreign silver *drachmae* were in circulation at Rome previous to their issue. A long succession of these silver pieces consisting of some thousand varieties from this period to the age of Gallienus, form the Roman silver, divided into Consular, or those struck under the Republic, and Imperial, or those from the time of Augustus. The earliest denarii having on one side the head of Rome, and on the other the Dioscuri, can be traced to B.C. 224, and 219. The earlier denarii have X or XVI. (16 asses) stamped behind them for their value, and ROMA on the reverse; the quinarius or piece of 5 asses about the size of a silver fourpence, has V. behind the head of Mars, and on the reverse a Victory, the sestertius of the size of a silver penny has HS. behind the head. These pieces

and marks were discontinued about the first cent. B.C. The tradition that Servius Tullius struck silver money at Rome [Varro in Chariso lib. I.] deserves no attention. The tribune Livius Drusus, sanctioned the alloy of $\frac{1}{2}$ of copper, and Antony allowed iron, but the debasement of the currency was restrained by the Gratidian Edict and the Cornelian Law. The denarii however continued tolerably pure till the time of Severus, although a slight corruption commenced with Didius Julian; their mean weight is 60 grs. Under Nero 7 denarii were coined from the Roman ounce of silver, later 8, and even more; denarii equal to $1\frac{1}{2}$ of the usual size and weight, or six sesterces, and called *argentei*, were struck by Caracalla, of a debased silver besides the usual size, the silver being half debased. Alexander Severus who reduced the taxation by one third, debased the silver in the same proportion by $\frac{1}{3}$ of its purity, but at the time of Valerian and Gallienus a national bankruptcy ensued, the denarii were debased to billon, of $\frac{1}{2}$ silver, the brass sesterces and dupondii, nummi incutiles, 1st and 2nd brass were suppressed. Aurelian made 525 of these base pieces equal to the *aureus*, by issuing a denarius of account equal to 20 or 21 of them, and marked XX-XXI-XXIV. From Claudius Gothicus to Diocletian, the denarii were of brass washed with silver the *nummi tincti*, and the successors of Constantine to prevent forgery of the public money made the denarii thinner and of larger size. Diocletian issued silver pieces of 48 grs., the *cententionales* or 'hundreds' marked xcvi, to show the proportion of alloy, 4 per cent. in the lb. of silver, with the denarius of 62 grs. Constantine added to the silver currency the *miliarenses*, or *miliarisia*, of 84 grs., 12 to the solidus, and the *siliqua*, or *keratia*, of 42 grs.; but 5 different denominations of his coins are known from their weight, and the confusion of the monetary system after and about his time baffles research. At the close of the Lower Empire they became very thin concave pieces of metal, the nummi scyphati, and the whole system of currency was altered.

The earliest Roman coins were of brass, *aes*, and heavy pieces *aes grave*. But there is great discrepancy about the time when it was introduced. Saturnus is said to have introduced it, and divided the solidus or pound into the semis or half pound. At the time of Servius Tullus, brass went by weight at Rome. (Timæus, in Plin, xxiii. c. 3.) Numa issued leather money *scortei*. Menenius Agrippa is said to have been buried by a subscription of sextantes, and the people subscribed quadrantes or farthings for P. Valerius. But the brass coinage of the Romans appears to have been derived from the Etruscan currency, and cannot be earlier than 353 B.C. The oldest currency was cast, not struck, and said to be impressed with an ox or sheep. (Varro, 'I. Vit. Pop. Re Rust,' lib. 2.) The following pieces have been found of the early series:—a decussis, having the head of Pallas, reverse a ship, weighing 38 Roman ounces; the quincussis impressed with two dolphins and two tridents, reverse, two chickens and two stars=4 lb. 8 oz. Roman; a quadrussis, on each side an ox, of 5 lb. 6 oz., and 4 lb. 3 oz.; a *tripondios* of 3 asses marked III. head of Pallas, reverse a ship, for an as of 3 ozs., head of Pallas and sword. The types of the rest of the currency are quite uniform, the *as* has the head of the double Janus, the *semis*, the letter S. head of Jupiter, the *triens*: (4 ounces) head of Pallas; the *quadrans* or farthing: (3 ounces) head of Hercules; the *sextans*: (2 ounces), head of Mercury, the ounce: head of Pallas, all have on the reverse the prow of a ship, alluding to the arrival of Janus or Saturn in Italy, and boys instead of crying heads or tails when they tossed for money cried heads or ships. Ases of 11 lb. 5 oz. exist, many of 3 and 4 ozs. showing that the reduction was gradual: after the 1st Punic war the *as* was reduced by the Lex Papiria to 1 oz., and to $\frac{1}{2}$ oz. from the time of Sylla to Pompey. (Cohen, 'Descr. gen. domn. de la Rep. Rom.,' 4to. Paris, 1857.) At the commencement of the Empire the names of the triumviri monetales were stamped on the coins; the *as*, the second brass coin, was struck of copper, the sestertius or first brass coin was struck of the Spanish orichalcum, and at the time of the Flavii the *as flavum* was of copper mixed with brass; the third brass coin, the quadrans, copper; the earlier bronze coin are alloyed with zinc, and lead was not introduced till the time of Severus.

I. The largest Roman brass coins after the fall of the Republic are the so-called first or large brass, the sestertii. These pieces were in use from the days of Augustus to Gallienus. Under the thirty tyrants they disappeared, but a new piece was issued by Diocletian called the follis, 24 of which went to the silver miliarensis, and each was half an ounce in weight and worth 40 noummia or small centimes. In the Augustan age it weighed nearly a Roman ounce, but it declined in weight under the later emperors, under Severus Alexander was one-third lighter, and reduced by Gallus to one-third of an ounce. Trajan Decius struck two—sextarii or quinarii of orichalcum. Originally it was struck from an alloy of copper and zinc, with a small quantity of lead, of which a greater quantity became introduced in the days of the Antonines. The types on the obverse generally present the portrait of the emperor, while the legends record his titles, how often he had exercised the consulship or tribunitian power, or been saluted emperor, by which the date of the coin can be determined. The reverse indicated the character of the reign, the deities, the virtues, the temples, sacrifices, consecrations, and apotheoses; the provinces, cities, rivers, ports, and bridges; indulgences, remission of taxes, and exhibitions of spectacles; the victories, harangues, expeditions, journeys of the emperor. The virtues being accorded by the adulation of the senate, and not by the censors of history, present

the moderation of Tiberius, the clemency of Vitellius, and the triumphs of Domitian, and are fortunately corrected by the pen of the historian.

The size of the sestertius allows scope for the skill of the artist. From Augustus to Nero the style improves, and continues excellent from Vespasian to Hadrian. After Commodus, the art declines till the fall of the Gordians; and the subsequent pieces exhibit a remarkable degeneracy, especially at the time of Gallienus, the portraits only showing any merit.

II. The next size to these coins is the so-called second or middle brass, consisting of two metals and two different denominations: the *dupondius*, *dibella*, or half sesterce, struck in brass, and the *as* of pure copper. The dupondius underwent the same changes as the sestertius till the time of Gallienus, when it was suppressed, having been reduced by Severus Alexander to $\frac{1}{3}$ of its weight. This series is important for being more continuous than the large brass, few imperial portraits being wanting, and some being absolutely requisite to complete the first brass series, as Agrippa, Tiberius, Pertinax, and some others. At the time of Diocletian, the term second brass is usually applied to the follis of $\frac{1}{4}$ oz. weight by collectors, and reappears from Aurelian to Anastasius, which circulated along with the brass denarius, first struck by Philip, equal to four sestertii.

III. This series consists of Roman semisses and quadrantes, although some have erroneously regarded them as the uncia. They are pieces issued by the moneyers under Augustus and Tiberius, and reappear under Caligula with imperial portraits, one of the finest being that of Nero; it is common under Domitian, Hadrian, and the Antonines, after which it disappears till the age of Decius. The greatest portion of the series, as arranged in cabinets, comprises the base denarii issued by Gallienus and the thirty Tyrants, down to the reign of Diocletian; after which period it is profusely abundant in types and varieties, and becomes the assarion under Diocletian and his successors, disappears with Julian III., and ceases to be distinct in the divisions of K. 20, I, 10 *nummia* of the follis. A complete series in 3rd brass is impossible, as no pieces of this size exist from the age of Hadrian till Gallienus. Many of the earlier specimens were struck by the moneyers, and several have no imperial portraits, but only heads of deities and SC. on the reverse; and with them the quadrantes, issued from the mines of Noricum, with the inscription METAL, are generally classed.

Coins of a larger size than the ordinary currencies have been called medallions, a word derived from the Italian *medaglione*, again derived from the Greek *metallon*. The decadrachms of Athens and Syracuse have been thus called, but the term is more properly applied to the large pieces of the Roman series. Some few of gold and silver occur under the upper Empire, but silver medallions are most prevalent after Constantine; one of the most remarkable and the heaviest being that of Priscus Attalus, in the British Museum. After the time of Hadrian, bronze medallions, heavy and thick pieces, struck by the emperor without the authority of the senate, and made of two metals appear. These are the ancient *missilia*, so called from being hurled into the amphitheatre. They are sometimes made of two metals, the outer portions for $\frac{1}{4}$ th or $\frac{1}{2}$ inch being of copper when the body is of bronze, or *vice versa*, and are often found set in flat disks measuring 6 inches diameter, and forming part of the standards of the manipuli and vexillations, being with the busts part of the sacred effigies placed in the chapels of the legions and adored by them. At the time of Severus they are often wholly or partially gilded, and sometimes ringed for suspension. They were also probably given as military rewards. These pieces are of great rarity and interest, but the subjects on them are the same or similar to the Roman first brass. They are ancient proofs or medals properly so called.

Another kind of medals are called by the numismatists *contorniati* "encircled," or *revocati*, and are about 2 inches in diameter. They are so named from a deep groove which runs between the legend and the border, often curtailing the letters of the legend, and the edge is generally flanged. Some rare examples have their subjects on both sides incuse. They have on the obverse the busts of deities, emperors, heroic personages, poets, or philosophers, and in the area the unexplained monogram P E, a palm branch, lion, and other symbols, punched or incised, and often inlaid in silver, and on the other figures groups and mythological subjects, probably copied from celebrated works of art then extant. A very prevalent type is that of a quadriga, alluding to the Circenses. Legends on the obverse refer to the bust represented; but many of those on the reverse are votive exclamations to charioteers or athletes, as VRSE VINCAS., OLYMPI NIKA., PETRONI PLACEAS. ("May you conquer, oh, Ursus! Olympius, conquer; Petronius, may you please"). They are supposed to have been struck from the time of Gratian, A.D. 375, to the reign of Anthemius, A.D. 472, the last emperor represented on them. The object for which they were struck is unknown, whether for throwing into the Circus, or presentation to successful charioteers. The portraits of Homer, Sallust, and Horace are found on them, but of late date and apocryphal character. These medals are often chased or imitated in the times of the renaissance. (Sabatier, J., 'Description Générale des Medallions contorniati,' 4to, 1860.)

Similar to the contorniati are a class of medallions of the size of the 3rd brass, having on one side numbers from i. to xxix., and on the other busts and other representations, chiefly of an indecent nature. These little pieces are called *spinthria*, and are supposed to have been

issued by Tiberius, or for the Floralia. Others, of the same size, were also struck for triumphs, the Saturnalia, and other popular occasions, or even for quack doctors. With these may be also classed leaden pieces, used as seals, tokens, or tickets (Eckhel, 'Doctr. Num. Vet.,' viii. 314), such as are said to have been issued by Agrippa, Nero, Hadrian, and others, for largesses to the populace. Money was thrown on great occasions into the arena of the circus and amphitheatre, gold being restricted to the emperor, while the consuls were only allowed to throw down silver.

The types of the Roman coins differ considerably from the Greek, commencing at a period when the arts were in a rapid state of decay, and the treatment more pictorial, as is shown by the numerous figures often introduced upon the reverse. While, too, the Greek autonomous coins represent deities, or animals, and emblems, the Roman coins assume an historical character, and abound with allegorical figures of mental qualities, as *spes*, or hope; *patientia*, patience; *providentia*, prudence; *fides*, faith; *letitia*, joy; while liberality, peace, honour, virtue, fortune, and the like, are portrayed by their respective figures; besides which, the principal deities of the Pantheon are represented, or public events as they appeared at the time, as prostrate princes, legionaries at the adlocutions or addresses, and the sacrifices of the Decennalia, the emperor on horseback in his decursio, and the various public buildings represented in a conventional manner. These are often accompanied with inscriptions recording the name of the deity or allegory represented. The types of the Roman coins are in fact more pictorial than Greek, but not so much so as modern medals, on which numerous figures and aerial perspective are introduced.

Besides the usual types, occasionally smaller impressions stamped from punches are found on coins. On the autonomous Greek series there are generally the types of other states, and were impressed to give the pieces currency in their territory; sometimes as many as three have been found on one coin, as ΠΕΡ for Pergamus, ΤΡΑΑ for Tralles, ΣΑΡ for Sardes. In the Roman series they appear as brands, the emperors countermarking the coins of their predecessors; while other marks, such as SC., SPQR., seem to indicate that the effigy or coin was cancelled. Besides these letters, and other marks, the defacements of possessors are found; but these are in letters incised, not in relief. At Rome, countermarks commence under Augustus and continue till Trajan, reappear in the Lower Empire under Justinian, and are found as late as Anastasius. Some marks are supposed to have been impressed by the *exploratores monetae*, as PR, M.PR, and BON, to indicate *moneta probata*, *probata*, approved, *bona*, good or passed, coin.

The inscriptions on the Roman coins are much more copious than those on the Greek autonomous. On the consular series they have the names of the personages represented, and the triumviri of the mint. On the imperial coins the inscriptions on the obverse have the name and titles of the emperor, which are sometimes continued on the reverse. These have the abridgments common to Roman inscriptions, as IMPERATOR, CAESAR, AVGVSTVS, CONSVL; D. N., dominus noster; P. F., Pius Felix; P. P., Pater Patriae; TRIBVNTIA POTESTATE; or TR. P., the same. The reverses of the bronze have always the S. C., referring to their being struck by Senatus Consultum, which is to be distinguished from the EX. S. C., showing that the type referred to some act of the senate. The other contractions are too numerous to be given, but REST. refers to the restoration of certain coins made by the emperors, either of the pieces coined by their predecessors or ancestors. The subject of the reverse has often a full inscription, as ÆQVITAS., SPES., AQVA TRAIANA, explaining the figure, but at the time of Philip single letters appear in the area of the coin, and seem to be the initial of the names of the mint, the first hitherto referred being those of Tarraco and Siscia on the coins of Probus. From this period till the close of the Byzantine empire they are constantly placed in the exergue, generally preceded by the form P., percussa, or pecunia, or S.M., sacra moneta, as S M A N T., sacra moneta Antiochensis tertium; or M-oneta only.

The principal mints are, ALEXANDRIA, ANTIOCHIA, AQUILEIA, ARELATUM, CONSTANTINOPOLIS, LONDINUM, LVGDUNUM, OSTIA, TREVIRI, THEVROPOLIS. The Latin mints have the initials of numerals indicative of their sizes, offices, or issues, and the Greek have A.B.Γ.Δ. for the same. From the time of Probus, XXI. the number of these pieces which went to the denarius are marked, and on the gold after Constantine OB, the Greek for 72 occurs on the solidus, after the name of the mint. Only one date of the A.V.C. DCCCLXXIV. is found on the Roman series. Some blunders occur, either the work of forgers or the result of official carelessness, as Consecratio for Consecratio, Mletam propugnatorum for Martem propugnatorum, Ianum Clusti for Clusit, Sousti for Faustina.

As the triumviri monetales could not impress upon the public money their own effigies, they placed upon it the most memorable events of their family history, and hence the aurei and argentei of this series present several remarkable types. The brass coinage is less interesting, the as has the head of Janus; the semis, Jupiter; the triens, Minerva; the quadrans, Hercules; the sextans, Mercury; the uncia, Minerva or Juno. All have the ship on the reverse. Those with the names of the triumviri monetales present no more interest. The older types of these denarii have the head of Rome on the obverse, and on the reverse a four-horse chariot, whence they were called quadrigati, or one of two horses, bigati, or the Dioscuri on horseback. Later types have on the obverse the heads of deities, personifications, as Piety

and slaves to a torturing death; and Constantine punished false coining as high treason with the penalty of confiscation, exile, or death, and reduced the thickness of the coins so that it might ring and prevent plating.

After the fall of the Roman Empire the separation of Europe into various small states gave rise to a currency like the autonomous coins of Greece. It is not possible to give a detailed account of the numerous types found in the modern series which has existed in Europe for the last 1400 years. The first French dynasty, the Merovingian, issued sous d'or, (solidus), demi-sous (semis), and tiers sous, trientes, struck by the great lords or moneyers, with their names and that of the mint, and imitating the coins of Anastasius. Under the Carolingian dynasty deniers of silver were introduced, and the sous d'or almost abandoned, and Charlemagne introduced his name in a monogram on the coins, A.D. 864. The dissolution of the empire of Charlemagne gave rise to the Italian and German series. During the commencement of the Capets the denier tournois with a Tower and Parisii, and oboles were chiefly in circulation. The royal portrait did not appear till Louis XII., and Anne of Brittany first placed the millesime or date of the Christian era on the currency in 1478. Besides the regal coins, the barons, bishops, and monasteries issued their own currency; but these were gradually suppressed by the crown. In the series there are a few bracteates, or thin coins of a leaf of gold or silver, struck in relief on one side and hollow on the other, and issued by religious houses, and *mereaux*, tokens, which under some circumstances were used for coin. The coins of Germany follow the French style; but the art is not so good. The early coins of Bohemia resemble the Anglo-Saxon: later ones have St. Wenceslas. Those of Hungary commencing with the 11th century, A.D., have the effigy of the monarchs. The coins of Poland commence with Boleslas the Great, imitate the Anglo-Saxon types, and have the portrait of the monarch. The early currency of Russia consisted of furs and coins; gold coins do not begin till the 10th century, A.D. They are imitated from the Byzantine currency; the silver, called *denga*, begin with the 14th century, are of oblong shape with the prince on horseback, Samson and the lion, Arabic legends; copper commences about the 15th century, and Peter the Great introduced the usual European types in the 18th century. In Italy the coins of the Gothic were succeeded by the Lombard kings, and those of the dukes of Benevento and Salerno, the Norman princes of the kingdoms of the two Sicilies, all imitated from the Byzantine currency; and the currency of Charlemagne, who forced the tributaries to adopt his monogram on the coins. At Rome, from the 11th to the 14th century, the currency was issued by the Senate till Innocent IV. regained the power; but as early as the 13th century the Pope coined in the Legations. From the 9th to the 11th century the prelates of Manheim, Aquileia, and Ascoli struck their own coins. A series of coins of Venice, comprising *sequins* and *gazettas* commence with the 12th century and terminate in the 19th, having for their normal type the Doge receiving the gonfalone, or standard from St. Mark. From the 12th to 14th century the Republic of Genoa and other free towns struck coins. Malta, given in 1551 to the Knights of St. John of Jerusalem, has a series with the arms and effigies of the Grand Masters.

The modern coins of Spain commence with the Visigoths, who entered it in A.D. 531, who struck a series of gold solidi imitated from the Byzantine, with their heads and those of the emperor on the reverse. The double heads disappear about A.D. 650, and give place to profile portraits, the monogram of the king's name, and the crown. The coins struck by the Mussulman princes belong to the Oriental series. The kingdoms of Castile, Arragon, and Majorca follow the usual mediæval types. The coins of Great Britain and Ireland have been already described [COIN]; the early pieces of Denmark, commencing with Harthacnut, A.D. 1036, resemble them. But from the end of the 10th to the 12th century numerous bracteates were issued, many by ecclesiastics; and crosses are the normal type from the middle of the 13th century, and crowns after 1280. In Sweden, the early types of the 11th century copy the Anglo-Saxon; but from the end of the 11th to the 14th century a great number of bracteates, and small pieces with the initials of the king's name, were in circulation. From 1365 the coins bear the arms of Sweden and the three crowns. The coins of Norway commence at the same time as those of Sweden, but are less interesting. Of the Crusaders, there are large bronze coins commencing with Tancred, 1110, and continuing with the various princes and nobles established in Greece and the East to the 15th century. The general series of types in the dark ages are imitations of the Byzantine—crosses, portraits, figures of saints, and heraldic emblems. The various changes and different values of modern coin belong rather to money than numismatics. Although, in reality, mediæval coins are much rarer than the Greek and Roman, they are less prized by amateurs, and few cabinets of them have been formed.

The Oriental coins comprise those struck in the East by the Mohammedans; these coins are flat thin pieces, like the later Byzantine pieces, and are called dirhems. They commence with the Ommiah race of khalifs, the earliest being the gold dinars of the 78th and the dirhems of the 79th year of the Hegira. Both sides are covered with inscriptions in the centre surrounded by a legend, the whole recording the Profession of the Faith, varied by extracts from the Koran, the name of the city and year in which they were struck. The coins of Seljuks have the sun in Leo; the Turkoman Ortokites and Atabegs, portraits

and devices rudely copied from Byzantine and other sources. The Mamluk Bahrites have occasionally a lion, in addition to their legends. The Norman kings of Sicily have mediæval types with Arabic legends. The later Turkish are distinguished by the *tograh* or complicated signature of the sultan. Some of the Persian have animals, as a fish, cock, camel, deer, and ox, in addition to inscriptions. The Patan dynasty, the kings of Jaunpur, have inscriptions only. Of the Moguls of Hindustan there is a fine series of gold mohurs, having on their obverse the twelve signs of the zodiac, struck by Jehangir in 1611. Of the sultans of Mysore, the most remarkable are the copper coins of Tippoo Saib, with an elephant. The earliest Hindu coins are those of the Gupta line, representing Brahminical deities. The coins of Southern India, Nepal, Assam, and Rangpur, have legends only. Of Tenasserim, there are large octagonal and circular tin coins, impressed on one side with a dragon and phoenix. The coins of China and Indo-China consist principally of the *tsien* or cash; but at the earliest period in China, copper knives (*taou*) and cloth-shaped pieces (*poou*) were in use. The cash have the value from A.D. 120, and the imperial name from A.D. 457; four characters, two meaning money, from A.D. 618. Under the Mogul and Manchou dynasty they have the name of the mint in Manchou on the reverse. There are only silver dollars of 1683, struck on the conquest of Formosa. The coins of Japan are flat gold plates called *obang* and *kobang*, and submultiples, the square *itzeboo*; the silver coins are flat rectangular pieces—*monme*, *giun*, and *nandiogiuns*; the *seni* cash like the Chinese, from 1636. The coins of the Corea date from 1116; of Annam, 1428; of Cochin, and Tunkin from 1740; of Java, from the 13th century, with Buddhistic figures to imitate the Chinese. Of Siam there are bent pieces of silver, stamped at the bend with ornaments.

The high prices paid for ancient coins gave rise to numerous forgeries in the 15th and 16th centuries, and many Italian artists, comprising Benvenuto Cellini, Valerio di Vicenza, Sebastiano Piombo, and others, especially G. Covino made false dies of Roman coins with great success, and issued the forgeries recognised as Paduans or Parmeggians by collectors. These, principally large brass, are detected by their thinner and rounder shape, closer and finer letters, and Italian style of work. Others retouched casts of true coins with the graver, and added a false patina, filing the edges. In the 18th century, Congornier, at Lyon, made gold coins of the Tyrants of the age of Gallienus, and La Roche and Devrieu at Florence, counterfeited the Roman large brass. Webber, Galli, and Caprara of Smyrna, are known as forgers of Greek coins. The forgeries of Beckker of Offenbach, who died in 1830, are by far the most numerous, consisting of upwards of 600 dies, and 331 pieces, and worth 2629*l.*, copied from the antique, principally in gold and silver, with some mediæval specimens distinguished by a coarser style of work, ignorance of details, expression, and letters. Greek medallions and coins were made by Neapolitan forgers, and false dies were in activity in 1830 at Syra. As few, if any of the Greek and Roman coins are found from the same die, the comparison of suspected struck coins in various cabinets, leads to the detection of forgeries of this class, in addition to the precautions of weighing the suspected pieces, and observing their correspondence with the standard and fineness of the true coins, to avoid which, however, Beckker often used for his blanks ancient coins of corresponding value.

The largest class of forgeries are casts made from antique coins, by making moulds of them in clay or plaster, and are executed with better success in gold and silver than in brass or copper, gold coins never having any ærugo, and the metal flowing more freely in the mould, and silver being easily oxydised by chemical agents so as to appear to have long lain in the earth, while the patina, or rust of bronze and copper, especially the *red rust* or protoxyde of copper, the hard crystalline character of which cannot be produced by chemical action, but only by the slow process, of centuries, *cannot be imitated*. All casts are deficient in weight, have smoothed edges, pitted fields, fused letters, and interstices more or less filled up, defects only to be concealed by the suspicious operations of filing the edges, tooling out with a graver the letters and features, and covering the whole with a false soft patina. The older deceptions of altering with a graving tool the portraits of common emperors into rare ones, tampering with the legends, or splitting two medals, giving rare and unusual reverses, of stamping different reverses or obverses, appears to have been abandoned, as too coarse to deceive, and are only found in old cabinets.

A coarser kind of forgeries were invented by the chasers and engravers of the 15th century, representing on one side the head of Priam, on the other a view of Troy, or Queen Dido and Carthage, Artemisia and the Mausoleum; such learned toys were, however, only calculated to deceive theoretical pedants. (Beauvais, 'La manière des discerners les Médailles Antiq.' 4to, Paris, 1739; 'Sopra i Moderni falsificatori di medaglie Greche,' 8vo, Fir., 1820.)

Cabinets are generally made of mahogany, oak and cedar being objectionable owing to the turpentine and pyroligneous acid they exude. The drawers, 3th inch thick, are pierced with circular holes 1½ inch in diameter, for autonomous Greek, and 1¾ inch in diameter for large brass; a small circular hole is left about ¼ inch in diameter, to allow of a coin being lifted by the finger, the holes are lined with movable pieces of cloth to prevent the rubbing of the coin. The larger and smaller sizes for medallions, silver pennies, dollars, and denarii are in proportion. As economy of space is always sought, each suite is arranged by itself, although the placing together of the entire currency of each

people or monarch, irrespective of sizes or metals, is more instructive: Greek coins are arranged geographically; the Roman gold, silver, and brass each in a series, modern coins according to countries, the coins of emperors according to the states or cities where struck.

Although it is not possible to give in this article any account of the value of ancient coins, yet some notions may be given of the value of the coins of Greece. The gold staters of cities sometimes fetch 30*l.* or 60*l.*, those of the kings are comparatively common, and Philip II., Alexander III., and Lysimachus, are worth little more than their weight in metal, while one of Mithridates has sold for 120*l.*; in silver tetradrachms vary from a few shillings to many pounds—those of Athens, Alexander, and Lysimachus, being worth about 16*s.* or 20*s.*, while a fine one of Myrrhina obtained 260*l.* Those of the kings are generally rare, and many obtain as much as 30*l.* or 40*l.*; the unique one of Cleopatra, mother of Antiochus VIII., cost 240*l.* The copper is only very valuable when beautifully preserved. In the Roman series the consular pieces, and the Roman gold and silver are not generally valuable, a collection of the first being worth on an average 3*l.* 10*s.* per piece, and that of the latter not more than 5*s.* The large brass series is more valuable, the second much less so, and the 3rd brass of little or no value. The average value of a mediæval collection is about 15*s.* per piece, and of medals about 10*s.* Collectors will indeed find some clue to the price of Greek and Roman medals in the works of Mionnet and Cohen, but the values are constantly varying, and increase according to the preservation of the coins, and must be sought for by examining priced catalogues of sales. As a general rule, the prices paid for coins and medals have been much enhanced in the last quarter of a century.

Although it is not possible to give the value of any of the great public collections of Europe, some idea of their worth may be derived from that of collections formed by individuals. The collection of Dr. Hunter, now at Glasgow, cost upwards of 21,000*l.*, that of the late Mr. Thomas sold for 17,304*l.*, that of the Earl of Pembroke for 5905*l.* 14*s.*, and the late Lord Northwick's Greek and Roman collection realised 9138*l.* 14*s.*; that of the Duke of Devonshire, 6945*l.* 6*s.* 8*d.*

The rarity of ancient coins depends on various causes, but is principally owing to the few struck from a peculiar die, owing to the poverty of certain States, of the short reigns of some princes, or the suppression of their coins by public authority. Of some Roman Emperors there are absolutely none in certain metals and sizes; bronze coins of Otho, for example, were never struck by the Senate, and the coins of Caligula were called in and destroyed by the same body; but in all cases preservation enhances in the highest degree the value of coins otherwise ordinary.

Ancient coins are discovered in the bosom of the earth, or in the bosom of rivers where they have been lost or hoarded by public or private misfortunes. Isolated discoveries are constantly being made by excavators, but sometimes they occur in great numbers; 30,000 gold staters of Lysimachus were found in a river of the ancient Dacia, 30,000 silver denarii in 1760, at Brest, 4000 aurei at Hornoy, 12,000 pennies of William the Conqueror at Beaworth, and 7000 Saxon coins at Cuerdale, not to mention minor finds. They present different appearances according to the locality; gold under all circumstances retains its colour, but sometimes requires the removal of a crust of iron or other substances which adhere to it; silver is so oxydised as to present a grayish black colour, and for the types to be legible, it must be cleaned by lemon juice, citric acid, or acetic acid, and some use sal ammoniac. Bronze and copper present a most varied appearance; from the beds of rivers, such as the Thames, they have a yellow or brown patina, and only require removing from the matters which surround them. From volcanic soils they come with a bright turquoise blue or green patina, which must not be touched when it is polished, and shows under its coat, like the varnish of a picture, all the contours of the type and legend. The yellow and brown patinas of other soils must be respected, but the green gritty rust which disfigures many copper coins may be successfully removed by placing the coins in 1 part of hydrochloric acid with 14 parts of water, watching the progress, and allowing them to remain a short time afterwards in ammonia. The use of the wire brush, of the knife or graver, may be also judiciously applied to cleaning brass coins.

The principal general works on the subject are—

(Hennin, *Manuel de Numismatique Ancienne*, 8vo, Paris, 1830; Grasset, *Handbuch der alten Numismatik*, 8vo, Lips. 1852-53; Werlhoff, *Handbuch der Griechischen Numismatik*, 8vo, Hanov., 1850; Barthélemy, *Manuel de Numismatique*, 16mo, Paris. [no date.]

NUN. [MONACHISM.]

NUNCIO (*Nunzio*, in Italian; *Nuntius*, in Latin) signifies a messenger, but is used more particularly to designate the ambassadors sent by the pope to foreign courts. The nuncio is generally a prelate of the court of Rome; if a cardinal, he is styled "legate." Previous to the council of Trent, the papal nuncios in foreign countries acted as judges, in the first instance, of matters which were within ecclesiastical jurisdiction; but since that time they have acted as judges of appeal from the decisions of the respective bishops, in those countries only which are subject to the decretals and discipline of the council of Trent. In those kingdoms and states, such as France, which, though Roman Catholic, hold themselves independent of the court of Rome in matters of discipline, the nuncio has no jurisdiction whatever, and has

ARTS AND SCI. DIV. VOL. V.

merely a diplomatic character, like the minister of any other foreign power. (Père Richard, 'Bibliothèque Sacrée,' art. 'Nonce.')

NUNCUPATIVE WILL. [WILL AND TESTAMENT.]

NUTATION. [PRECESSION AND NUTATION.]

NUX VOMICA, ALKALOIDS OF. The beans and bark of the nux vomica, and of several other species of the genus *strychnos* [STRYCHNOS, in NAT. HIST. DIV.] contain three alkaloids, namely, (1) *strychnine*, (2) *brucine*, (3) *igasurine*. It is to these alkaloids that the poisonous properties of the plants are due. In the beans of the *strychnos nux vomica* the alkaloids exist in combination with *igasuric acid*, but in the bark chiefly with gallic acid.

(1). *Strychnine*. ($C_{42}H_{22}N_2O_4$). *Vauqueline*, *Tetanine*. This alkaloid was discovered by Pelletier and Caventou in 1818. Several processes for extracting it from nux vomica have been described, but the following by Mr. Horsley is, perhaps, the most convenient yet published. An acetic extract is first made by kneading up the nux vomica powder with its own weight of commercial acetic acid; this is thinned out with five or six times its bulk of water, and the whole allowed to digest for a few days. The clear liquor must then be decanted off, and an equal quantity of fresh water poured on the mass and allowed to digest for a day or two longer, or till all soluble matter is extracted; the clear liquor is then decanted, mixed with the former liquor, and the whole evaporated to a syrupy consistence. When the resulting solution is cold, dilute with an equal bulk of water, add excess of liquid ammonia, and set by for a day or two that the strychnine may crystallise out. Next pass through a calico filter to separate the dark green mother liquor, and digest the resinoid residuum in hot dilute acetic acid and filter. The strychnine and brucine may now be precipitated by solution of potash, or the strychnine only by the addition of solution of chromate of potash, when a chromate of strychnine will be obtained free from brucine, provided the liquid, which retains the brucine, be tolerably acid. Chromic acid may be readily separated from the strychnine by digesting the chromate of strychnine in ammonia, when the alkaloid is left in a state of snowy whiteness.

The amount of strychnine present in nux vomica, St. Ignatius' beans, and other derivatives of the *strychnos* tribe, varies from five-tenths to one and a half per cent.

Strychnine is colourless and inodorous, but of intensely bitter taste, one part in one million of water possessing decided bitterness. Its crystalline form is octohedral, or square prismatic. It is only slightly soluble in water, one part requiring seven thousand parts of cold water, or nearly three thousand parts of hot water, for its solution; in round numbers one grain of strychnine is soluble in one pint of cold water. It is insoluble in absolute alcohol, pure ether, or alkaline solutions; but soluble in the essential oils, chloroform, and ordinary alcohol. Strychnine exerts lævo-rotation on a polarised ray, with double the power of brucine. It fuses when heated, but is not sublimeable. Distilled with hydrate of potash it furnishes quinoline.

Strychnine is an exceedingly powerful poison, and has of late years been much used for criminal purposes. A great deal of attention has consequently been bestowed upon it by chemists, and its detection in the various parts of an animal that has been killed by it is now as certain and as easy as that of any of the well-known mineral poisons. The following process by Messrs. Rodgers and Girdwood is one of several, but is perhaps more convenient than some others:—The substance operated upon is digested with dilute hydrochloric acid, one to ten, until it is apparently fluid; the liquid is then filtered and evaporated to dryness over a water-bath, treated with spirit as long as anything is dissolved, the filtered tincture evaporated as before, and the residue treated with water and filtered; this aqueous solution must now be rendered alkaline by ammonia, and agitated in a bottle, or long tube, with about half an ounce of chloroform; after subsidence the chloroform is drawn off by means of a pipette, transferred to an evaporating basin, and the chloroform expelled over a water-bath; the residue must then be moistened with concentrated sulphuric acid, and exposed for some hours to the temperature of a water-bath, by which proceeding all organic matter except the strychnine is destroyed. The charred mass is then treated with water, and the solution filtered to separate the carbon; excess of ammonia is now added, and the solution again agitated with about one drachm of chloroform; if on evaporating a small portion of this chloroform solution, and treating the residue with concentrated sulphuric acid, any charring takes place, the preceding process must be repeated until the strychnine from the chloroform solution remains in a perfectly pure state. Pure strychnine, obtained as just described, or in any other manner, is at once recognised by the following reactions:—The first is known as the *colour test*, and consists in evaporating to dryness a solution of a fragment of the alkaloid on a white plate, and then allowing to flow over it a small quantity of sulphuric acid previously slightly coloured with bichromate, or red prussiate, of potash; on coming into contact, a beautiful violet colour, fading into a rose-red, is produced, if any quantity greater than the one-thousandth of a grain of strychnine is present. Some other oxidising agents produce the same effect. A solution of strychnine also gives characteristic precipitates with tannic acid, terchloride of gold, chromate or bichromate of potash, carbazotic acid, iodine, &c., but these should all be confirmed by the application of the colour test. The *physiological test* recommended by Marshall Hall, consists in placing frogs in the suspected solution, or injecting small quantities of the

fluid into the thoracic or abdominal cavity, when tetanic convulsions will ensue if strychnine be present. Strychnine is a powerful base; it precipitates most metallic oxides from their salts, and combines with acids to form a well-marked series of compounds, many of which have been described by Abel and Nicholson.

Hydrofluorate of strychnine ($C_{12}H_{22}N_2O_4, 4HF, +4Aq.$) crystallises in prisms on evaporating a solution of strychnine in hydrofluoric acid.

Hydrochlorate of strychnine ($C_{12}H_{22}N_2O_4, HCl + 3Aq.$), crystallises in needles, is neutral to test-paper, and even more soluble in water than the sulphate.

Sulphates of strychnine. A neutral salt containing ($2C_{12}H_{22}N_2O_4, S_2O_6, 2HO + 14Aq.$) is formed on digesting excess of strychnine in dilute sulphuric acid; it crystallises in small rectangular prisms. The acid salt containing ($C_{12}H_{22}N_2O_4, S_2O_6, 2HO$) is produced when strychnine is dissolved in excess of dilute sulphuric acid; it crystallises in long needles. *Sulphate of strychnine and copper* is a crystalline salt formed when strychnine is boiled with sulphate of copper.

Chromate of strychnine ($C_{12}H_{22}N_2O_4, CrO_3, HO$) falls as a yellow precipitate when chromate of potash is added to a salt of strychnine. It is soluble in hot water, crystallising out in beautiful orange needles on cooling. A *bichromate* also exists.

Nitrate of strychnine ($C_{12}H_{22}N_2O_4, HO, NO_5$) is obtained by saturating strychnine with dilute nitric acid. It crystallises in needles. Heated with concentrated nitric acid it forms nitrate of *nitro-strychnine*.

The following are the principal remaining compounds of strychnine with acids and with metallic salts.

Chloroplatinate of strychnine . . .	$C_{12}H_{22}N_2O_4, HCl, PtCl_2$
Chloropalladate of strychnine . . .	$C_{12}H_{22}N_2O_4, HCl, PdCl$
Chloraurate of strychnine . . .	$C_{12}H_{22}N_2O_4, HCl, AuCl_3$
Chloromercurates of strychnine . . .	$\alpha. C_{12}H_{22}N_2O_4, 2HgCl$
	$\beta. C_{12}H_{22}N_2O_4, HCl, 2HgCl$
	$\gamma. 2C_{12}H_{22}N_2O_4, S_2O_6, 2HO, 4HgCl$
Perchlorate of strychnine . . .	$C_{12}H_{22}N_2O_4, HO, ClO_7 + 2Aq.$
Hydrobromate of strychnine . . .	$C_{12}H_{22}N_2O_4, HBr$
Hydriodate of strychnine . . .	$C_{12}H_{22}N_2O_4, HI$
Nitrate of strychnine and silver . . .	$C_{12}H_{22}N_2O_4, AgO, NO_5$
Phosphates of strychnine . . .	$\alpha. C_{12}H_{22}N_2O_4, 3HO, PO_5 + 4Aq.$
	$\beta. 2C_{12}H_{22}N_2O_4, 2HO, PO_5 + 18Aq.$
	$\gamma. 2C_{12}H_{22}N_2O_4, C_4O_6, 2HO$
Oxalates of strychnine . . .	$\alpha. C_{12}H_{22}N_2O_4, C_4O_6, 2HO$
	$\beta. 4C_{12}H_{22}N_2O_4, 4HCy, 2FeCy + 16Aq.$
	$\gamma. 3C_{12}H_{22}N_2O_4, 2HCy, 2FeCy + 5Aq.$
Ferrocyanates of strychnine . . .	$\alpha. C_{12}H_{22}N_2O_4, HgCy$
	$\beta. C_{12}H_{22}N_2O_4, HCl, HgCl$
	$\gamma. C_{12}H_{22}N_2O_4, HCl, 4HgCy$
Hydargyrocyanoates of strychnine . . .	$C_{12}H_{22}N_2O_4, HSCyS$
Hydrosulphocyanate of strychnine . . .	$\alpha. 2C_{12}H_{22}N_2O_4, C_8H_6O_{12} + nAq.$
	$\beta. C_{12}H_{22}N_2O_4, C_8H_6O_{12} + 6Aq.$
Tartrates of strychnine . . .	

Chlorine, bromine, and iodine derivatives of strychnine. *Chloro-strychnine* ($C_{12}H_{21}ClN_2O_4$) is formed by the action of chlorine upon solution of hydrochlorate of strychnine; it combines with acids to form salts. *Bromostrychnine* is produced when bromine is made to act upon hydrochlorate of strychnine. *Iodostrychnine*, or *iodide of strychnine* ($2C_{12}H_{22}N_2O_4, I_2$), obtained on triturating strychnine with iodine, crystallises from alcohol in orange-coloured scales.

Methyl and ethyl derivatives of strychnine. According to M. Stahl-schmidt these compounds are not in the slightest degree poisonous. They are powerfully basic. With iodide of ethyl, strychnine gives a crystalline *hydriodate of ethylostrychnia*, or *iodide of ethylostrychnium* ($C_{12}H_{21}(C_2H_5)N_2O_4, HI$), and this with oxide of silver yields bihydrate of ethylostrychnia, or rather hydrated oxide of ethylostrychnium ($C_{12}H_{22}(C_2H_5)N_2O_4, O, HO$). Hydrated oxide of *methylo-strychnium* is best obtained by decomposing the sulphate with baryta water.

Strychnic acid is the name given by M. Rousseau to the product of the action of heat upon a mixture of strychnine, chlorate of potash, and sulphuric acid.

2. *Brucine* ($C_{40}H_{26}N_2O_8 + 8Aq.$). *Canimarine, Vomine.* This alkaloid was discovered by Pelletier and Caventou, in the bark of the false angustura, which is the bark of the *strychnos nux vomica*, and not, as was supposed when its name was given to it, of the *brucia antidysenterica*. This alkaloid, like strychnine, is found combined with gallic acid in the bark, and with igasuric acid in the fruits of some of the different species of *strychnos*.

It may be obtained by evaporation and crystallisation of the mother liquor from the precipitation of chromate of strychnine, already described; or, according to Thénard, by dissolving the soluble portion of the nux vomica bark in water, mixing the solution with a little oxalic acid, and evaporating it to the consistence of a syrup. This is to be treated, at 32° Fahr., with anhydrous alcohol, which dissolves everything but the oxalate of brucine. This salt is then to be boiled in water with magnesia; the precipitated brucine is to be dissolved in boiling alcohol, from which it crystallises on cooling.

When a little water is added to the alcoholic solution of brucine, and the mixture is put to evaporate spontaneously, the brucine crystallises in colourless, transparent, oblique four-sided prisms. By rapid evaporation, pearly scales or crystals, in the form of cauliflowers, are obtained. These crystals contain water; they have a strong bitter taste, which remains for a long time. When the hydrate is heated rather below 212° Fahr., it melts and loses about 16 per cent. of its weight of water; the fused mass is a non-crystallised body resembling wax in appearance. It is decomposed by a strong heat.

Brucine requires 850 parts of cold water and 500 of boiling water for solution. It is readily soluble in alcohol, and even in spirit of wine of specific gravity 0.88: the volatile oils dissolve a small portion of it, but neither the fixed oils nor ether take it up. One of the distinguishing characters of brucine is that the red or yellow colour which nitric acid imparts to it is changed to a fine violet by protochloride of tin.

The salts of brucine have a bitter taste, and most of them are crystalline; they are decomposed not only by the alkalies and alkaline earths, but by morphine and strychnine, which precipitate brucine.

Nitrate of brucine ($C_{40}H_{26}N_2O_8, 2HONO_5 + 4Aq.$) is obtained by adding nitric acid to brucine. It crystallises in quadrilateral prisms, terminated by dihedral summits. When heated, it becomes first red, then black, and afterwards detonates with disengagement of light.

Hydrochlorate of brucine ($C_{40}H_{26}N_2O_8, HCl$) crystallises in quadrilateral prisms obliquely truncated, which are sometimes as fine as hair. It does not alter by exposure to the air.

Sulphates of brucine. The neutral sulphate ($2C_{40}H_{26}N_2O_8, S_2O_6, 2HO, + 14Aq.$) is very soluble in water, and crystallises in long quadrilateral needles. Alcohol dissolves it in small quantity. The *supersulphate* crystallises readily when a little acid is added to the neutral sulphate.

Oxalate of brucine crystallises in long needles, especially when it contains excess of acid.

Phosphates of brucine. The neutral salt ($2C_{40}H_{26}N_2O_8, 3HO, PO_5$) occurs in prisms; but the supersalt crystallises in large square tables, which dissolve readily in water, and effloresce by exposure to the air.

Acetate of brucine is very soluble, but uncrystallisable.

Many other salts of brucine, corresponding to the strychnine salts, have also been obtained. *Bromobrucine* ($C_{40}H_{25}BrN_2O_8$) occurs in needles; and the *iodobrucines* are amorphous powders. The nitro-compound, or *cacotheline* as it is termed, is the product of the action of strong nitric acid upon brucine; nitrate of methyl, oxalic acid, binoxide of nitrogen, and water, being at the same time produced. The composition of cacotheline is ($C_{10}H_{22}(NO_4)_2N_2O_{10}$); it is a feeble base. *Ethyl- and methyl-brucine* are obtained in the same way as, and have properties similar to, the corresponding strychnine salts.

3. *Igasurine.* According to M. Desnoix, this alkaloid is contained in the mother liquors from the preparation of strychnine and brucine. He gives it the name igasurine from *igasur*, the native name of St. Ignatius' beans [*STRYCHNOS Ignatii*, in NAT. HIST. DIV.]; and describes it as a colourless precipitate, becoming crystalline if left in the mother liquor. Igasurine differs from brucine in being more soluble in boiling water, and in being precipitated by bicarbonate of potash or soda in presence of tartaric acid; it otherwise much resembles brucine. Its physiological action is intermediate between strychnine and brucine. M. Schutzenberger has examined several specimens of igasurine, and asserts that by treating with cold water he obtained nine new alkaloids or *igasurines* from them. Their formulæ and relations to strychnine and brucine are as follow:—

Strychnine	$C_{12}H_{22}N_2O_4$
Brucine	$C_{40}H_{26}N_2O_8 + 8HO$
Igasurine, a (very little soluble)	$C_{44}H_{26}N_2O_8 + 6HO$
" b (slightly soluble)	$C_{36}H_{24}N_2O_{14} + 6HO$
" c (readily soluble)	$C_{36}H_{24}N_2O_8 + 6HO$
" d " "	$C_{34}H_{32}N_2O_{16} + 6HO$
" e " "	$C_{36}H_{26}N_2O_8 + 6HO$
" f " "	$C_{42}H_{30}N_2O_8 + 6 \text{ or } 8HO$
" g (very little soluble)	$C_{48}H_{22}N_2O_{12} + 6HO$
" h (readily soluble)	$C_{42}H_{26}N_2O_{12} + 6HO$
" i " "	$C_{40}H_{26}N_2O_{14} + 6HO$

The above bases are said to resemble brucine in their chemical characters, but are more soluble in water and alcohol. M. Schutzenberger considers them as products of the successive transformations of brucine under the influence of vital force, and suspects the existence of several more.

Igasuric acid may be prepared from any of the mother liquors resulting from the preparation of the nux vomica alkaloids. Such solutions are saturated with magnesia, boiled, evaporated, precipitated by acetate of lead, the precipitate decomposed by sulphuretted hydrogen, and the filtered liquor evaporated to a syrupy consistence. *Igasuric acid* then slowly crystallises out in hard crystalline grains, very soluble in water and alcohol, and of an acid styptic taste. The *igasurates* are mostly soluble in alcohol or water, and crystallise with difficulty.
